

## CS10: The Beauty and Joy of Computing

### Lecture #7: Algorithm Complexity

TA Jon Kotker (2010-09-27)

#### LEDs + Math = Art

Leo Villareal combines modern LED control systems to produce contemporary modern art. The exhibit is on display at the San Jose Museum of Art.

## BIG IDEA

- Many ways to do the same thing = many *algorithms* to accomplish the same task.
- Example: Distributing candy!
- Example: Searching through a list of numbers to find a specific number.
  - *Linear* search (list is unsorted): Go through the list number by number and check if each number is The One.
  - *Binary* search (list is sorted): Look at the middle of the list. If it is not The One, break the list into two smaller halves and ignore the irrelevant half.
  - Any other algorithms?

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 2

## MAKING A DECISION

How do we decide which algorithm to use?

- Which is easier to implement?
- Which takes less time?
- Which uses up less space (memory)?
- Which gives a more precise answer?
- Which of the above questions even *matter*?

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 3

## WHAT DO YOU THINK?

Which of the factors below is most important in making a choice between two algorithms?

- Which is easier to implement?
- Which takes less time?
- Which uses up less space (memory)?
- Which gives a more precise answer?
- I don't know / I don't have an opinion.

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 4

## RUNTIME ANALYSIS

One commonly used criterion in making a decision is **runtime** – how much time does the algorithm take to run and finish its task?

Computers are most useful for large inputs, so find the runtime of the algorithm on large inputs.

*How do we do that?*

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 5

## RUNTIME ANALYSIS

Time the algorithm with a stopwatch! But...

- Different computers will have different runtimes. ☹
- Same computer can have different runtime on the same input. ☹
- Need to implement the algorithm first so that we can run it. o\_o;

*Solution:* Need to somehow *abstract* the computer away from the algorithm.

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 6

## RUNTIME ANALYSIS

*Idea:* Do not focus on how long the algorithm takes on one input. Instead, focus on how the **worst-case** runtime of the algorithm *scales* as we scale the input.

*Why?* Abstracts the computer out. A good algorithm should work well, no matter what the computer = a good recipe should produce a great dish, no matter what the kitchen.

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 7

## RUNTIME ANALYSIS

*Idea:* Do not focus on how long the algorithm takes on one input. Instead, focus on how the **worst-case** runtime of the algorithm *scales* as we scale the input.

*Why?* Computers are mainly used for large sets of data. The runtime of an algorithm should scale "reasonably" as we make the dataset even larger, or else we need to improve/discard that algorithm.

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 8

Dangerous for Math majors.

**A LOT OF APPROXIMATION AHEAD!**

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 9

## ARITHMETIC OPERATIONS

*Key Idea:* As the input scales, arithmetic operations take approximately the same time. Arithmetic operations are **constant-time** operations.

*Another Key Idea:* We only care about how the runtime of the block scales as the input *scales*!

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 10

## LAUNDRY

*It Must Be Done*

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 11

## WASHING LOADS

If each load takes about the same time to launder, how does the runtime scale as the number of loads doubles? Triples?

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 12

## WASHING LOADS

laundry **number** loads

*Key Idea:* The runtime of the algorithm scales by the same amount as the size of its input scales.

Doing laundry is a **linear-time** operation in the number of loads.

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 13

## FINDING CLOTHES TO WEAR

find a good pair to wear in **number** shirts and pants

How does the **worst-case** total time to find a good pair scale as the number of shirts and pants doubles?

1. Stays the same.
2. Doubles.
3. Halves.
4. Quadruples.
5. Buh?

*Hint:* For each shirt that I own, how many pants do I have to match against it?

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 14

## FINDING CLOTHES TO WEAR

find a good pair to wear in **number** shirts and pants

*Key Idea:* If I have 3 shirts and pants, there are 9 different combinations that I can try, because for *each* shirt, I can try on 3 pants to match with it.

Double it: If I have 6 shirts and pants, there are 36 different combinations that I can try.

If I double the number of shirts and pants that I have, then the number of different combinations that I can try **quadruples**.

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 15

## FINDING CLOTHES TO WEAR

find a good pair to wear in **number** shirts and pants

*Key Idea:* The runtime of the algorithm scales by the **square** of the amount that the input scales by.

Finding a good pair of clothes to wear is a **quadratic-time** algorithm in the number of shirts and pants.

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 16

## LAUNDRY

*It Has Been Done*

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 17

## RUNTIME ANALYSIS

What is the runtime of this script?

1. Constant in num.
2. Linear in num.
3. Quadratic in num.
4. Buh?

UC Berkeley CS10 "The Beauty and Joy of Computing" - Algorithm Complexity 18

## RUNTIME ANALYSIS

What is the runtime of this script?

```
repeat 10 times
  change num by 1
```

1. Constant in num.
2. Linear in num.
3. Quadratic in num.
4. Buh?

## RUNTIME ANALYSIS

What is the runtime of this script?

```
repeat num times
  repeat num times
    change num by 1
```

1. Constant in num.
2. Linear in num.
3. Quadratic in num.
4. Buh?

## RUNTIME ANALYSIS

What is the runtime of this script?

```
repeat num times
  repeat num - 1 times
    change num by 1
```

1. Constant in num.
2. Linear in num.
3. Quadratic in num.
4. Buh?

## IT'S ALL APPROXIMATE!

Which is better: a **linear-time** algorithm or a **quadratic-time** algorithm?

Input Size (N)	10	100	1000	10000	100000
Linear (msec)	C	10C	100C	1000C	10000C
Quadratic (msec)	C	100C	10000C	10 <sup>6</sup> C	10 <sup>8</sup> C

As the input size increases, the quadratic-time algorithm takes so much more time than the linear-time algorithm that the linear-time algorithm is *negligible* in comparison.

## IT'S ALL APPROXIMATE!

Which is better: a **linear-time** algorithm or a **quadratic-time** algorithm?

Input Size (N)	10	100	1000	10000	100000
Linear (msec)	C	10C	100C	1000C	10000C
Quadratic (msec)	C	100C	10000C	10 <sup>6</sup> C	10 <sup>8</sup> C

Since we only consider large sized inputs, expressions like  $N^2 - N$  or  $N^2 + N$  are considered approximately equal to  $N^2$  and thus **quadratic-time**; the linear-time part is ignored.

## RUNTIME ANALYSIS (EXTRA)

What is the runtime of this algorithm to find the factorial of a number?

```
factorial of num
if num > 0
  set answer to 1
  set current to 1
  repeat until current > num
    set answer to answer * current
    change current by 1
report answer
```

1. Constant in the number.
2. Linear in the number.
3. Quadratic in the number.
4. Buh?
