Last Time in Lecture 15

Vector supercomputers

- Vector register versus vector memory
- Scaling performance with lanes
- Stripmining
- Chaining
- Masking
- Scatter/Gather

Types of Parallelism

- Instruction-Level Parallelism (ILP)
 - Execute independent instructions from one instruction stream in parallel (pipelining, superscalar, VLIW)
- Thread-Level Parallelism (TLP)
 - Execute independent instruction streams in parallel (multithreading, multiple cores)
- Data-Level Parallelism (DLP)
 - Execute multiple operations of the same type in parallel (vector/SIMD execution)
- Which is easiest to program?
- Which is most flexible form of parallelism?
 - i.e., can be used in more situations
- Which is most efficient?
 - i.e., greatest tasks/second/area, lowest energy/task

Resurgence of DLP

- Convergence of application demands and technology constraints drives architecture choice
- New applications, such as graphics, machine vision, speech recognition, machine learning, etc. all require large numerical computations that are often trivially data parallel
- SIMD-based architectures (vector-SIMD, subword-SIMD, SIMT/GPUs) are most efficient way to execute these algorithms

Packed SIMD Extensions

- Short vectors added to existing ISAs for microprocessors
- Use existing 64-bit registers split into 2x32b or 4x16b or 8x8b
 - Lincoln Labs TX-2 from 1957 had 36b datapath split into 2x18b or 4x9b
 - Newer designs have wider registers
 - 128b for PowerPC AltiVec, Intel SSE2/3/4
 - 256b for Intel AVX
- Single instruction operates on all elements within register

Multimedia Extensions versus Vectors

- Limited instruction set:
 - no vector length control
 - no strided load/store or scatter/gather
 - unit-stride loads must be aligned to 64/128-bit boundary
- Limited vector register length:
 - requires superscalar dispatch to keep multiply/add/load units busy
 - loop unrolling to hide latencies increases register pressure
- Trend towards fuller vector support in microprocessors
 - Better support for misaligned memory accesses
 - Support of double-precision (64-bit floating-point)
 - New Intel AVX spec (announced April 2008), 256b vector registers (expandable up to 1024b)

DLP important for conventional CPUs

- Prediction for x86 processors, from Hennessy & Patterson, 5th edition

– *Note: Educated guess, not Intel product plans!*

- TLP: 2+ cores / 2 years
- DLP: 2x width / 4 years
- DLP will account for more mainstream parallelism growth than TLP in next decade.
 - SIMD –single-instruction multiple-data (DLP)
 - MIMD- multiple-instruction multiple-data (TLP)

Graphics Processing Units (GPUs)

- Original GPUs were dedicated fixed-function devices for generating 3D graphics (mid-late 1990s) including high-performance floating-point units
 - Provide workstation-like graphics for PCs
 - User could configure graphics pipeline, but not really program it
- Over time, more programmability added (2001-2005)
 - E.g., New language Cg for writing small programs run on each vertex or each pixel, also Windows DirectX variants
 - Massively parallel (millions of vertices or pixels per frame) but very constrained programming model
- Some users noticed they could do general-purpose computation by mapping input and output data to images, and computation to vertex and pixel shading computations
 - Incredibly difficult programming model as had to use graphics pipeline model for general computation

General-Purpose GPUs (GP-GPUs)

- In 2006, Nvidia introduced GeForce 8800 GPU supporting a new programming language: CUDA
 - “Compute Unified Device Architecture”
 - Subsequently, broader industry pushing for OpenCL, a vendor-neutral version of same ideas.
- Idea: Take advantage of GPU computational performance and memory bandwidth to accelerate some kernels for general-purpose computing
- Attached processor model: Host CPU issues data-parallel kernels to GP-GPU for execution
- This lecture has a simplified version of Nvidia CUDA-style model and only considers GPU execution for computational kernels, not graphics
 - Would probably need another course to describe graphics processing

Simplified CUDA Programming Model

- Computation performed by a very large number of independent small scalar threads (*CUDA threads* or *microthreads*) grouped into *thread blocks*.

```
// C version of DAXPY loop.
```

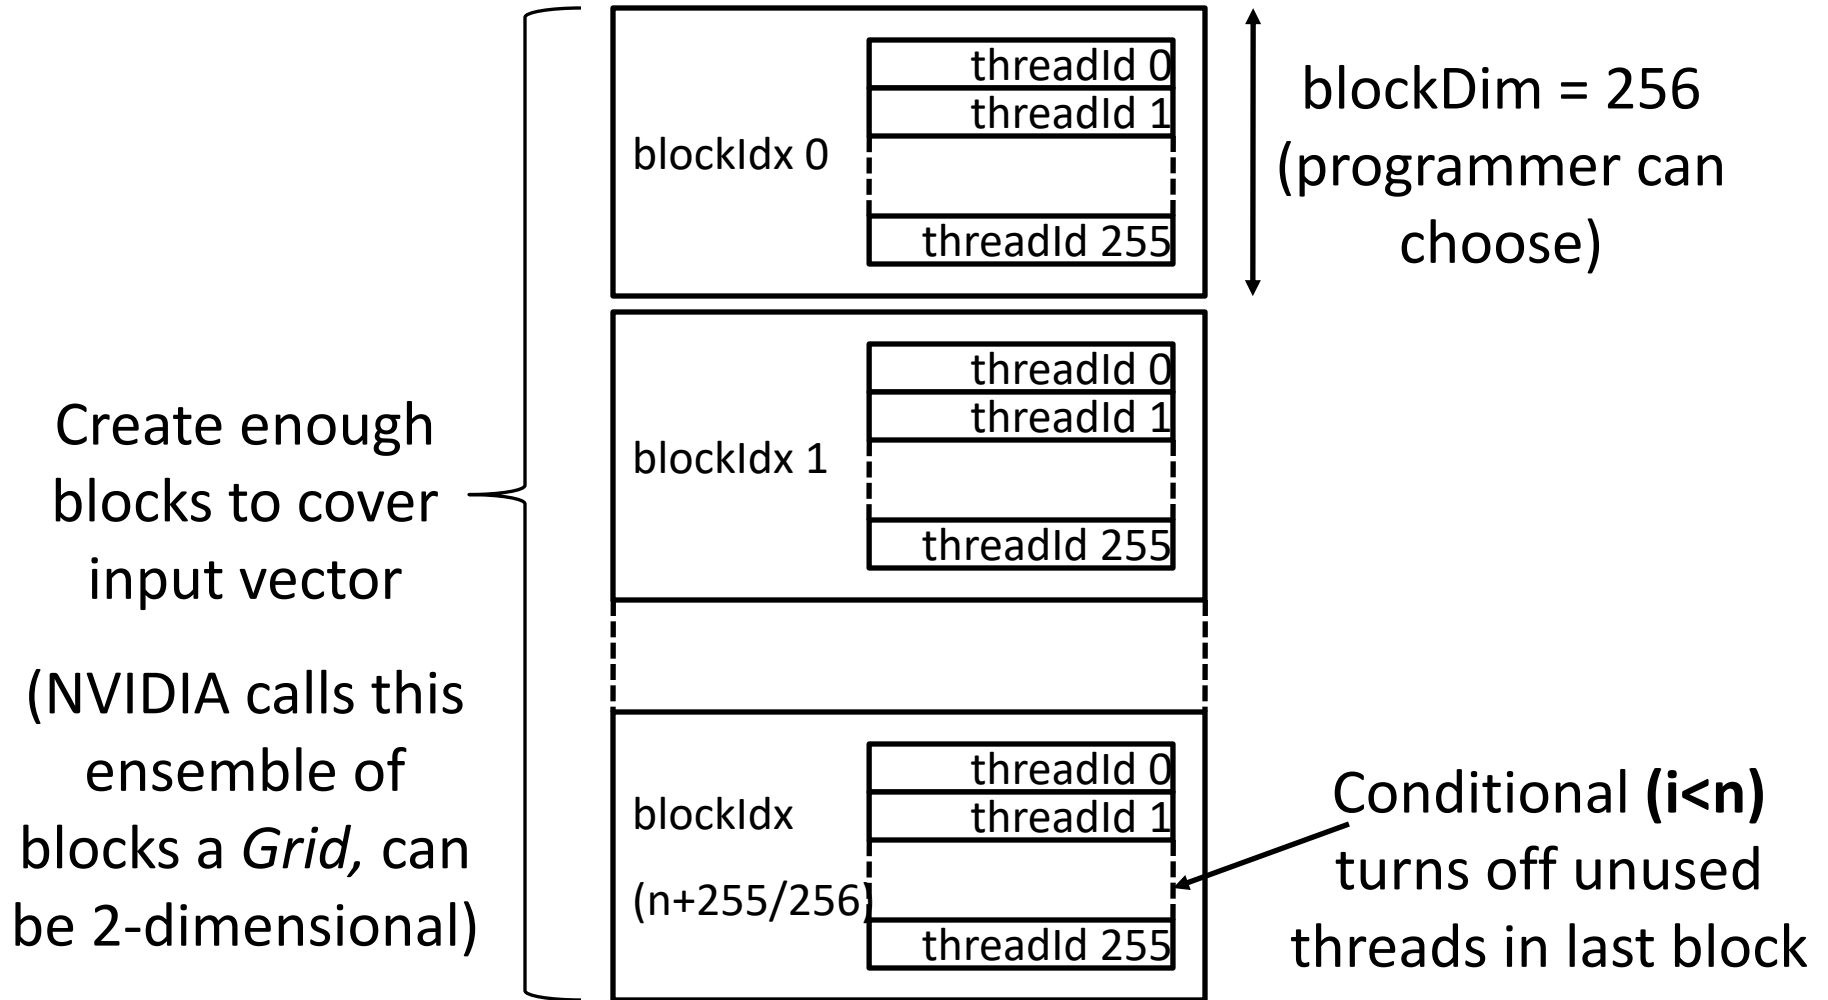

```
void daxpy(int n, double a, double*x, double*y)
{ for (int i=0; i<n; i++)
    y[i] = a*x[i] + y[i]; }
```

```
// CUDA version.
```

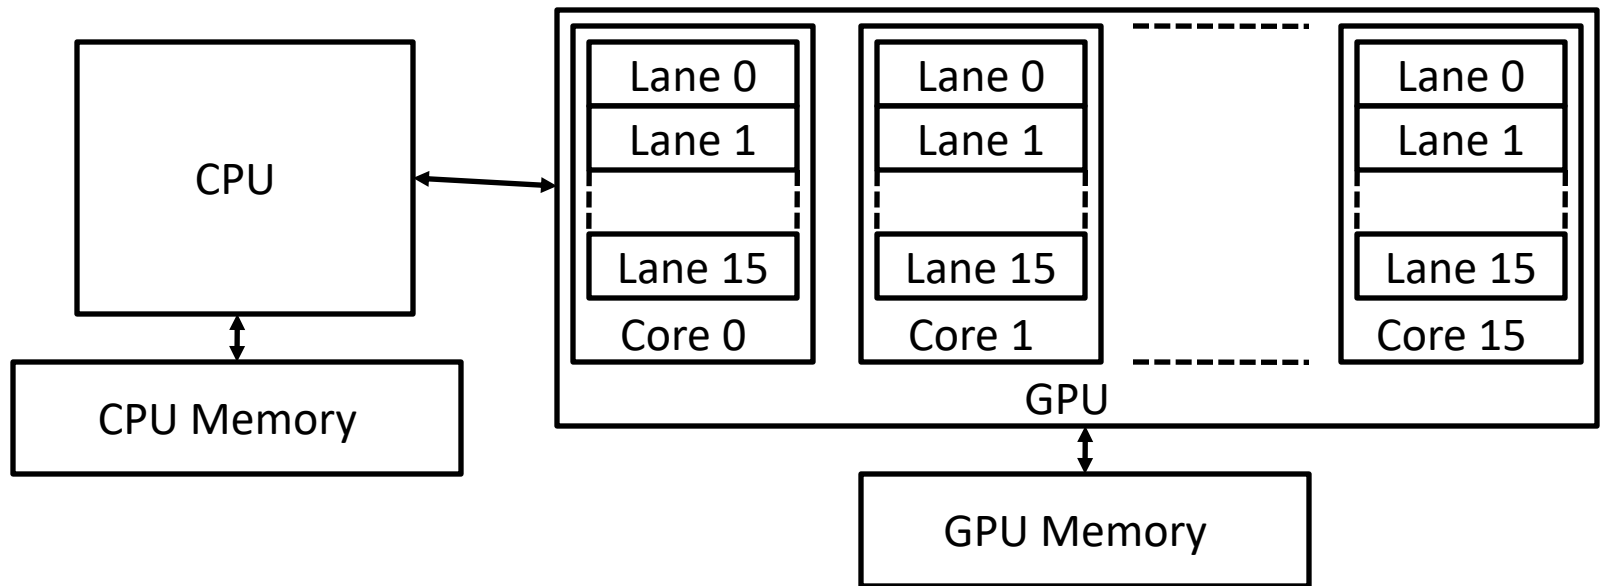

```
__host__ // Piece run on host processor.
int nblocks = (n+255)/256; //256 CUDA threads/block
daxpy<<<nblocks,256>>>(n,2.0,x,y);
```

```
__device__ // Piece run on GP-GPU.
void daxpy(int n, double a, double*x, double*y)
{ int i = blockIdx.x*blockDim.x + threadIdx.x;
  if (i<n) y[i]=a*x[i]+y[i]; }
```

Programmer's View of Execution

Hardware Execution Model

- GPU is built from multiple parallel cores, each core contains a multithreaded SIMD processor with multiple lanes but with no scalar processor
 - some adding “scalar coprocessors” now
- CPU sends whole “grid” over to GPU, which distributes thread blocks among cores (each thread block executes on one core)
 - Programmer unaware of number of cores

Historical Retrospective, Cray-2 (1985)

- 243MHz ECL logic
- 2GB DRAM main memory (128 banks of 16MB each)
 - Bank busy time 57 clocks!
- Local memory of 128KB/core
- 1 foreground + 4 background vector processors

“Single Instruction, Multiple Thread” (SIMT)

- GPUs use a SIMT model, where individual scalar instruction streams for each CUDA thread are grouped together for SIMD execution on hardware (NVIDIA groups 32 CUDA threads into a *warp*)

Implications of SIMT Model

- All “vector” loads and stores are scatter-gather, as individual μ threads perform scalar loads and stores
 - GPU adds hardware to dynamically coalesce individual μ thread loads and stores to mimic vector loads and stores
- Every μ thread has to perform stripmining calculations redundantly (“am I active?”) as there is no scalar processor equivalent

CS152 Administrivia

- PS 4 due Friday April 5 in Section
- Lab 4 out on Friday
- Lab 3 due Monday April 8

CS252 Administrivia

Next week readings: Cray-1, VLIW & Trace Scheduling

Conditionals in SIMT model

- Simple if-then-else are compiled into predicated execution, equivalent to vector masking
- More complex control flow compiled into branches
- How to execute a vector of branches?

Branch divergence

- Hardware tracks which μ threads take or don't take branch
- If all go the same way, then keep going in SIMD fashion
- If not, create mask vector indicating taken/not-taken
- Keep executing not-taken path under mask, push taken branch PC+mask onto a hardware stack and execute later
- When can execution of μ threads in warp reconverge?

NVIDIA Instruction Set Arch.

- ISA is an abstraction of the hardware instruction set
 - “Parallel Thread Execution (PTX)”
 - opcode.type d,a,b,c;
 - Uses virtual registers
 - Translation to machine code is performed in software
 - Example:

```

shl.s32      R8, blockIdx, 9      ; Thread Block ID * Block size (512 or 29)
add.s32      R8, R8, threadIdx    ; R8 = i = my CUDA thread ID
ld.global.f64 RD0, [X+R8]         ; RD0 = X[i]
ld.global.f64 RD2, [Y+R8]         ; RD2 = Y[i]
mul.f64 R0D, RD0, RD4 ; Product in RD0 = RD0 * RD4 (scalar a)
add.f64 R0D, RD0, RD2 ; Sum in RD0 = RD0 + RD2 (Y[i])
st.global.f64 [Y+R8], RD0         ; Y[i] = sum (X[i]*a + Y[i])
  
```

Conditional Branching

- Like vector architectures, GPU branch hardware uses internal masks
- Also uses
 - Branch synchronization stack
 - Entries consist of masks for each SIMD lane
 - I.e. which threads commit their results (all threads execute)
 - Instruction markers to manage when a branch diverges into multiple execution paths
 - Push on divergent branch
 - ...and when paths converge
 - Act as barriers
 - Pops stack
- Per-thread-lane 1-bit predicate register, specified by programmer

Example

```
if (X[i] != 0)
    X[i] = X[i] - Y[i];
else X[i] = Z[i];
```

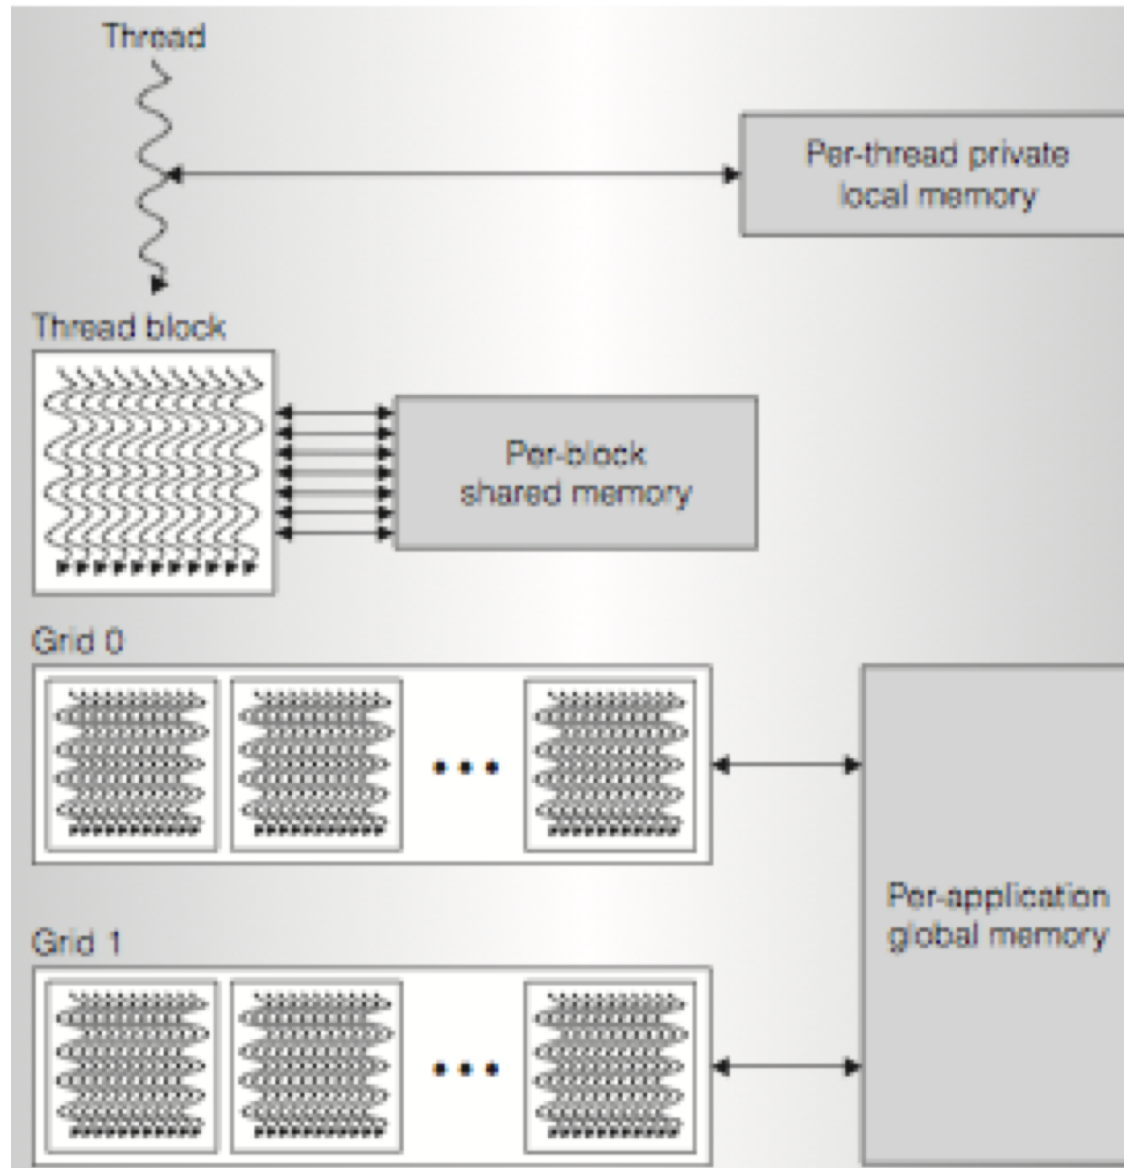

ld.global.f64	RD0, [X+R8]	; RD0 = X[i]
setp.neq.s32	P1, RD0, #0	; P1 is predicate register 1
@!P1, bra	ELSE1, *Push	; Push old mask, set new mask bits
		; if P1 false, go to ELSE1
ld.global.f64	RD2, [Y+R8]	; RD2 = Y[i]
sub.f64	RD0, RD0, RD2	; Difference in RD0
st.global.f64	[X+R8], RD0	; X[i] = RD0
@P1, bra	ENDIF1, *Comp	; complement mask bits
		; if P1 true, go to ENDIF1
ELSE1:	ld.global.f64 RD0, [Z+R8]	; RD0 = Z[i]
	st.global.f64 [X+R8], RD0	; X[i] = RD0
ENDIF1:	<next instruction>, *Pop	; pop to restore old mask

Warps are multithreaded on core

- One warp of 32 μ threads is a single thread in the hardware
- Multiple warp threads are interleaved in execution on a single core to hide latencies (memory and functional unit)
- A single thread block can contain multiple warps (up to 512 μ T max in CUDA), all mapped to single core
- Can have multiple blocks executing on one core

GPU Memory Hierarchy

[Nvidia, 2010]

SIMT

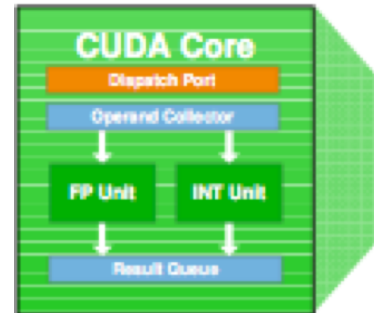

- Illusion of many independent threads
- But for efficiency, programmer must try and keep μ threads aligned in a SIMD fashion
 - Try and do unit-stride loads and store so memory coalescing kicks in
 - Avoid branch divergence so most instruction slots execute useful work and are not masked off
