# CS162 <br> Operating Systems and Systems Programming 

## Final Exam Review

May 4, 2012
Mosharaf Chowdhury and Karthik Reddy http://inst.eecs.berkeley.edu/~cs162

## Final Exam

- Friday May 11 11:30-2:30 PM in 230 Hearst Gym
- Two double-sided handwritten pages of notes
- Closed book
- Comprehensive
- All lectures, discussions, projects, readings, handouts,

## Topics

- Synchronization
- Primitives, Deadlock
- Memory management
- Address translation, Caches, TLBs, Demand Paging
- Distributed Systems
- Naming, Security, Networking
- Filesystems
- Disks, Directories
- Transactions

## Synchronization Primitives

## Definitions

- Synchronization: using atomic operations to ensure cooperation between threads
- Mutual Exclusion: ensuring that only one thread does a particular thing at a time
- One thread excludes the other while doing its task
- Critical Section: piece of code that only one thread can execute at once
- Critical section is the result of mutual exclusion
- Critical section and mutual exclusion are two ways of describing the same thing

## Semaphores

- Semaphores are a kind of generalized lock
- First defined by Dijkstra in late 60s
- Main synchronization primitive used in original UNIX
- Definition: a Semaphore has a non-negative integer value and supports the following two operations:
$-P()$ : an atomic operation that waits for semaphore to become positive, then decrements it by 1
" Think of this as the wait() operation
-V() : an atomic operation that increments the semaphore by 1 , waking up a waiting $P$, if any
" This of this as the signal() operation
- Note that $P()$ stands for "proberen" (to test) and $V()$ stands for "verhogen" (to increment) in Dutch

## Condition Variables

- Condition Variable: a queue of threads waiting for something inside a critical section
- Key idea: allow sleeping inside critical section by atomically releasing lock at time we go to sleep
- Contrast to semaphores: Can't wait inside critical section
- Operations:
- Wait (\&lock) : Atomically release lock and go to sleep. Reacquire lock later, before returning.
- Signal (): Wake up one waiter, if any
- Broadcast (): Wake up all waiters
- Rule: Must hold lock when doing condition variable ops!

## Mesa vs. Hoare monitors

- Hoare-style (most textbooks):
- Signaler gives lock, CPU to waiter; waiter runs immediately
- Waiter gives up lock, processor back to signaler when it exits critical section or if it waits again
- Mesa-style (most real operating systems):
- Signaler keeps lock and processor
- Waiter placed on ready queue with no special priority
- Practically, need to check condition again after wait

## Deadlock

## Four requirements for Deadlock

- Mutual exclusion
- Only one thread at a time can use a resource.
- Hold and wait
- Thread holding at least one resource is waiting to acquire additional resources held by other threads
- No preemption
- Resources are released only voluntarily by the thread holding the resource, after thread is finished with it
- Circular wait
- There exists a set $\left\{T_{1}, \ldots, T_{n}\right\}$ of waiting threads
" $T_{1}$ is waiting for a resource that is held by $T_{2}$
" $T_{2}$ is waiting for a resource that is held by $T_{3}$
"...
" $T_{n}$ is waiting for a resource that is held by $T_{1}$

## Banker's Algorithm for Preventing Deadlock

- Allocate resources dynamically
- Evaluate each request and grant if some ordering of threads is still deadlock free afterward
- Technique: pretend each request is granted, then run deadlock detection algorithm, substituting ([Max node $]-\left[\right.$ Alloc $\left._{\text {node }}\right] \leq[$ Avail $]$ ) for ([Request $\left.{ }_{\text {node }}\right] \leq[$ Avail $]$ ) Grant request if result is deadlock free (conservative!)
- Keeps system in a "SAFE" state, i.e. there exists a sequence $\left\{T_{1}, T_{2}, \ldots T_{n}\right\}$ with $T_{1}$ requesting all remaining resources, finishing, then $T_{2}$ requesting all remaining resources, etc..
- Algorithm allows the sum of maximum resource needs of all current threads to be greater than total resources

## Memory Multiplexing, Address Translation

## Important Aspects of Memory Multiplexing

- Controlled overlap:
- Processes should not collide in physical memory
- Conversely, would like the ability to share memory when desired (for communication)
- Protection:
- Prevent access to private memory of other processes
" Different pages of memory can be given special behavior (Read Only, Invisible to user programs, etc).
" Kernel data protected from User programs
" Programs protected from themselves
- Translation:
- Ability to translate accesses from one address space (virtual) to a different one (physical)
- When translation exists, processor uses virtual addresses, physical memory uses physical addresses
- Side effects:
" Can be used to avoid overlap
" Can be used to give uniform view of memory to programs

## Why Address Translation?

Translation Map 1
OS data
Translation Map 2
OS heap \&
Stacks
Physical Address Space

## Dual-Mode Operation

- Can an application modify its own translation maps?
- If it could, could get access to all of physical memory
- Has to be restricted somehow
- To assist with protection, hardware provides at least two modes (Dual-Mode Operation):
- "Kernel" mode (or "supervisor" or "protected")
- "User" mode (Normal program mode)
- Mode set with bits in special control register only accessible in kernel-mode
- User $\rightarrow$ Kernel: System calls, Traps, or Interrupts

## Caches, TLBs

## Review: Sources of Cache Misses

- Compulsory (cold start): first reference to a block
- "Cold" fact of life: not a whole lot you can do about it
- Note: When running "billions" of instruction, Compulsory Misses are insignificant
- Capacity:
- Cache cannot contain all blocks access by the program
- Solution: increase cache size
- Conflict (collision):
- Multiple memory locations mapped to same cache location
- Solutions: increase cache size, or increase associativity
- Two others:
- Coherence (Invalidation): other process (e.g., I/O) updates memory
- Policy: Due to non-optimal replacement policy

## Direct Mapped Cache

- Cache index selects a cache block
- "Byte select" selects byte within cache block
- Example: Block Size=32B blocks
- Cache tag fully identifies the cached data
- Data with same "cache index" shares the same cache entry - Conflict misses

## Set Associative Cache

- N-way set associative: N entries per Cache Index
- $N$ direct mapped caches operates in parallel
- Example: Two-way set associative cache
- Two tags in the set are compared to input in parallel
- Data is selected based on the tag result

## Fully Associative Cache

- Fully Associative: Every block can hold any line
- Address does not include a cache index
- Compare Cache Tags of all Cache Entries in Parallel
- Example: Block Size=32B blocks
- We need N 27-bit comparators
- Still have byte select to choose from within block

## Where does a Block Get Placed in a Cache?

- Example: Block 12 placed in 8 block cache 32-Block Address Space:

Block
111111111122222222233
no. 01234567890123456789012345678901

Direct mapped:
block 12 (01100) can go only into block 4 ( $12 \bmod 8$ )

Block
01234567
no.

tag index

Set associative: block 12 can go anywhere in set 0 (12 mod 4)

Fully associative:
block 12 can go anywhere

Block 01234567
no.

Set Set Set Set $\begin{array}{llll}0 & 1 & 2\end{array}$ tag index

## Review: Caching Applied to Address Translation

- Problem: address translation expensive (especially multi-level)
- Solution: cache address translation (TLB)
- Instruction accesses spend a lot of time on the same page (since accesses sequential)
- Stack accesses have definite locality of reference
- Data accesses have less page locality, but still some...

## TLB organization

- How big does TLB actually have to be?
-Usually small: 128-512 entries
-Not very big, can support higher associativity
- TLB usually organized as fully-associative cache
-Lookup is by Virtual Address
-Returns Physical Address
- What happens when fully-associative is too slow?
-Put a small (4-16 entry) direct-mapped cache in front
-Called a "TLB Slice"
- When does TLB lookup occur?
-Before cache lookup?
- In parallel with cache lookup?

## Reducing translation time further

- As described, TLB lookup is in serial with cache lookup:

Virtual Address

Physical Address

- Machines with TLBs go one step further: they overlap TLB lookup with cache access.
- Works because offset available early

## Overlapping TLB \& Cache Access

- Here is how this might work with a 4 K cache:

- What if cache size is increased to 8 KB ?
- Overlap not complete
- Need to do something else. See CS152/252
- Another option: Virtual Caches
- Tags in cache are virtual addresses
- Translation only happens on cache misses

## Putting Everything Together

## Page Tables \& Address Translation

Physical

## Translation Look-aside Buffer

## Virtual Address:

## Caching

Virtual Address:

## Demand Paging

## Demand Paging

- Modern programs require a lot of physical memory
- Memory per system growing faster than 25\%-30\%/year
- But they don't use all their memory all of the time
-90-10 rule: programs spend $90 \%$ of their time in $10 \%$ of their code
- Wasteful to require all of user's code to be in memory
- Solution: use main memory as cache for disk

## Demand Paging Mechanisms

- PTE helps us implement demand paging
- Valid $\Rightarrow$ Page in memory, PTE points at physical page
- Not Valid $\Rightarrow$ Page not in memory; use info in PTE to find it on disk when necessary
- Suppose user references page with invalid PTE?
- Memory Management Unit (MMU) traps to OS
» Resulting trap is a "Page Fault"
- What does OS do on a Page Fault?:
" Choose an old page to replace
" If old page modified (" $\mathrm{D}=1$ "), write contents back to disk
" Change its PTE and any cached TLB to be invalid
" Load new page into memory from disk
" Update page table entry, invalidate TLB for new entry
" Continue thread from original faulting location
- TLB for new page will be loaded when thread continued!
- While pulling pages off disk for one process, OS runs another process from ready queue
" Suspended process sits on wait queue

## Steps in Handling a Page Fault

## Page Replacement Policies

- FIFO (First In, First Out)
- Throw out oldest page. Be fair - let every page live in memory for same amount of time.
- Bad, because throws out heavily used pages instead of infrequently used pages
- MIN (Minimum):
- Replace page that won't be used for the longest time
- Great, but can't really know future...
- Makes good comparison case, however
- LRU (Least Recently Used):
- Replace page that hasn't been used for the longest time
- Programs have locality, so if something not used for a while, unlikely to be used in the near future.
- Seems like LRU should be a good approximation to MIN.

## Example: FIFO

- Suppose we have 3 page frames, 4 virtual pages, and following reference stream:
-ABCABDADBCB
- Consider FIFO Page replacement:

| Ref: <br> Page: | A | B | C | A | B | D | A | D | B | C | B |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{1}$ | A |  |  |  |  | D |  |  |  | C |  |
| 2 |  | B |  |  |  |  | A |  |  |  |  |
| $\mathbf{3}$ |  |  | C |  |  |  |  |  | B |  |  |

- FIFO: 7 faults.
- When referencing $D$, replacing $A$ is bad choice, since need $A$ again right away

## Example: MIN

- Suppose we have the same reference stream:

$$
-A B C A B D A D B C B
$$

- Consider MIN Page replacement:

| Ref: <br> Page: | A | B | C | A | B | D | A | D | B | C | B |
| ---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{1}$ | A |  |  |  |  |  |  |  |  |  |  |
| $\mathbf{C}$ |  | C |  |  |  |  |  |  |  |  |  |
| $\mathbf{3}$ |  |  | C |  |  | D |  |  |  |  |  |

- MIN: 5 faults
- Look for page not referenced farthest in future.
- What will LRU do?
- Same decisions as MIN here, but won't always be true!

## When will LRU perform badly?

- Consider the following: A B C D A B C D A B C D
- LRU Performs as follows (same as FIFO here):

| Ref: <br> Page: | A | B | C | D | A | B | C | D | A | B | C | D |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{1}$ | A |  |  | D |  |  | C |  |  | B |  |  |
| $\mathbf{2}$ |  | B |  |  | A |  |  | D |  |  | C |  |
| $\mathbf{3}$ |  |  | C |  |  | B |  |  | A |  |  | D |

- Every reference is a page fault!
- MIN Does much better:

| Ref: <br> Page: | A | B | C | D | A | B | C | D | A | B | C | D |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{1}$ | A |  |  |  |  |  |  |  |  | B |  |  |
| $\mathbf{2}$ |  | B |  |  |  |  | C |  |  |  |  |  |
| $\mathbf{3}$ | losharat Chow | C | D |  |  |  |  |  |  |  |  |  |

## Adding Memory Doesn’t Always Help Fault Rate

- Does adding memory reduce number of page faults?
- Yes for LRU and MIN
- Not necessarily for FIFO! (Belady's anomaly)

| Page: | A | B | C | D | A | B | E | A | B | C | D | E |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{1}$ | A |  |  | D |  |  | E |  |  |  |  |  |
| 2 |  | B |  |  | A |  |  |  |  | C |  |  |
| 3 |  |  | C |  |  | B |  |  |  |  | D |  |
| Page: | A | B | C | D | A | B | E | A | B | C | D | E |
| 1 | A |  |  |  |  |  | E |  |  |  | D |  |
| 2 |  | B |  |  |  |  |  | A |  |  |  | E |
| 3 |  |  | C |  |  |  |  |  | B |  |  |  |
| 4 |  |  |  | D |  |  |  |  |  | C |  |  |

- After adding memory:
- With FIFO, contents can be completely different
- In contrast, with LRU or MIN, contents of memory with X pages are a subset of contents with $\mathrm{X}+1$ Page

## Implementing LRU \& Second Chance

- Perfect:
- Timestamp page on each reference
- Keep list of pages ordered by time of reference
- Too expensive to implement in reality for many reasons
- Second Chance Algorithm:
- Approximate LRU
" Replace an old page, not the oldest page - FIFO with "use" (reference) bit
- Details
- A "use" bit per physical page
- On page fault check page at head of queue
" If use bit=1 $\rightarrow$ clear bit, and move page at tail (give the page second chance!)
" If use bit=0 $\rightarrow$ replace page
- Moving pages to tail still complex

## Clock Algorithm

- Clock Algorithm: more efficient implementation of second chance algorithm
- Arrange physical pages in circle with single clock hand
- Details:
- On page fault:
" Advance clock hand (not real time)
" Check use bit: $1 \rightarrow$ used recently; clear and leave it alone
$0 \rightarrow$ selected candidate for replacement
- Will always find a page or loop forever?
- What if hand moving slowly?
- Good sign or bad sign?
" Not many page faults and/or find page quickly
- What if hand is moving quickly?
- Lots of page faults and/or lots of reference bits set

## $\mathbf{N}^{\text {th }}$ Chance version of Clock Algorithm

- $\mathrm{N}^{\text {th }}$ chance algorithm: Give page N chances
- OS keeps counter per page: \# sweeps
- On page fault, OS checks use bit:
" $1 \Rightarrow$ clear use and also clear counter (used in last sweep)
" $0 \Rightarrow$ increment counter; if count=N, replace page
- Means that clock hand has to sweep by N times without page being used before page is replaced
- How do we pick N?
- Why pick large N? Better approx to LRU
" If $N \sim 1 K$, really good approximation
- Why pick small N? More efficient
" Otherwise might have to look a long way to find free page
- What about dirty pages?
- Takes extra overhead to replace a dirty page, so give dirty pages an extra chance before replacing?
- Common approach:
" Clean pages, use $\mathrm{N}=1$
" Dirty pages, use $\mathrm{N}=2$ (and write back to disk when $\mathrm{N}=1$ )

## Thrashing

- If a process does not have "enough" pages, the page-fault rate is very high. This leads to:
- low CPU utilization
- operating system spends most of its time swapping to disk
- Thrashing $\equiv$ a process is busy swapping pages in and out
- Questions:
- How do we detect Thrashing?
- What is best response to Thrashing?

## Locality In A Memory-Reference Pattern

- Program Memory Access Patterns have temporal and spatial locality
- Group of Pages accessed along a given time slice called the "Working Set"
- Working Set defines minimum number of pages needed for process to behave well
- Not enough memory for Working Set $\Rightarrow$ Thrashing
- Better to swap out process?

## Working-Set Model

```
page reference table
```

- $\Delta \equiv$ working-set window $\equiv$ fixed number of page references
- Example: 10,000 instructions
- $W S_{i}$ (working set of Process $P_{i}$ ) = total set of pages referenced in the most recent $\Delta$ (varies in time)
- if $\Delta$ too small will not encompass entire locality
- if $\Delta$ too large will encompass several localities
- if $\Delta=\infty \Rightarrow$ will encompass entire program
- $D=\Sigma\left|W S_{j}\right| \equiv$ total demand frames
- if $D>$ memory $\Rightarrow$ Thrashing
- Policy: if $D>$ memory, then suspend/swap out processes
- This can improve overall system behavior by a lot!

## File Systems

Review: Magnetic Disk Characteristic

- Cylinder: all the tracks under the head at a given point on all surface
- Read/write data is a three-stage process:

- Seek time: position the head/arm over the proper track (into proper cylinder)
- Rotational latency: wait for the desired sector to rotate under the read/write head
- Transfer time: transfer a block of bits (sector) under the read-write head
- Disk Latency $=$ Queuing Time + Controller time + Seek Time + Rotation Time + Xfer Time

- Highest Bandwidth:
- transfer large group of blocks sequentially from one track

05/04/2011 Mosharaf Chowdhury and Karthik Reddy CS162 ©UCB Spring 2012 Final Exam Review. 71

## Building a File System

- File System: OS layer that transforms block interface of disks into Files, Directories, etc.
- File System Components
-Disk Management: collecting disk blocks into files
- Naming: Interface to find files by name, not by blocks
- Protection: Layers to keep data secure
- Reliability/Durability
- How do users access files?
-Sequential Access: bytes read in order (most file accesses)
- Random Access: read/write element out of middle of array
- Goals:
- Maximize sequential performance
-Easy random access to file
-Easy management of file (growth, truncation, etc)

## Multilevel Indexed Files (UNIX 4.1)

- Multilevel Indexed Files: (from UNIX 4.1 BSD)
- Key idea: efficient for small files, but still allow big files
- File hdr contains 13 pointers

- Fixed size table, pointers not all equivalent
- This header is called an "inode" in UNIX
- File Header format:
- First 10 pointers are to data blocks
- Ptr 11 points to "indirect block" containing 256 block ptrs
- Pointer 12 points to "doubly indirect block" containing 256 indirect block ptrs for total of 64 K blocks
- Pointer 13 points to a triply indirect block (16M blocks)

## Example of Multilevel Indexed Files

- Sample file in multilevel indexed format:
- How many accesses for block \#23? (assume file header accessed on open)?
" Two: One for indirect block, one for data
- How about block \#5?
» One: One for data
- Block \#340?
» Three: double indirect block, indirect block, and data

- UNIX 4.1 Pros and cons
- Pros: Simple (more or less)

Files can easily expand (up to a point)
Small files particularly cheap and easy

- Cons: Lots of seeks

Very large files must read many indirect blocks (four I/O's per block!)

## File Allocation for Cray-1 DEMOS

Basic Segmentation Structure: Each segment contiguous on disk

- DEMOS: File system structure similar to segmentation
- Idea: reduce disk seeks by
" using contiguous allocation in normal case
" but allow flexibility to have non-contiguous allocation
- Cray-1 had 12ns cycle time, so CPU:disk speed ratio about the same as today (a few million instructions per seek)
- Header: table of base \& size (10 "block group" pointers)
- Each block chunk is a contiguous group of disk blocks
- Sequential reads within a block chunk can proceed at high speed - similar to continuous allocation
- How do you find an available block group?
- Use freelist bitmap to find block of 0's.

## Large File Version of DEMOS

- What if need much bigger files?
- If need more than 10 groups, set flag in header: BIGFILE " Each table entry now points to an indirect block group
- Suppose 1000 blocks in a block group $\Rightarrow 80 \mathrm{~GB}$ max file
" Assuming 8KB blocks, 8byte entries $\Rightarrow$
(10 ptrs $\times 1024$ groups/ptr $\times 1000$ blocks/group)* $8 \mathrm{~K}=80 \mathrm{~GB}$
- Discussion of DEMOS scheme
- Pros: Fast sequential access, Free areas merge simply Easy to find free block groups (when disk not full)
- Cons: Disk full $\Rightarrow$ No long runs of blocks (fragmentation), so high overhead allocation/access
- Full disk $\Rightarrow$ worst of 4.1BSD (lots of seeks) with worst of continuous allocation (lots of recompaction needed)

## Directory Structure

- Not really a hierarchy!
- Many systems allow directory structure to be organized as an acyclic graph or even a (potentially) cyclic graph
- Hard Links: different names for the same file
"Multiple directory entries point at the same file
- Soft Links: "shortcut" pointers to other files
" Implemented by storing the logical name of actual file
- Name Resolution: The process of converting a logical name into a physical resource (like a file)
- Traverse succession of directories until reach target file
- Global file system: May be spread across the network

## Networking

# How Does a Client Communicate with Servers? 

- A: Via transport protocol (e.g., UDP, TCP, ...)
- Transport protocol in a nutshell:
- Allow two application end-points to communicate
» Each application identified by a port number on the machine it runs
- Multiplexes/demultiplexes packets from/to different processes using port numbers
- Can provide reliability, flow control, congestion control
- Two main transport protocols in the Internet
- User datagram protocol (UDP): just provide multiplexing/ demultiplexing, no reliability
- Transport Control Protocol (TCP): provide reliability, flow control, congestion control

## Transport Layer

- DNS server runs at a specific port number, i.e., 53 - Most popular DNS server: BIND (Berkeley Internet Name Domain)
- Assume client (browser) port number 1234

## How do UDP packets Get to Destination?

- A: Via network layer, i.e., Internet Protocol (IP)
- Implements datagram packet switching
- Enable two end-hosts to exchange packets
» Each end-host is identified by an IP address
» Each packets contains destination IP address
» Independently routes each packet to its destination
- Best effort service
» No deliver guarantees
» No in-order delivery guarantees

## Network (IP) Layer (cont’d)

- Assume DNS server runs on machine 128.15.11.12
- Client configured with DNS server IP address
- Client runs on machine 16.25.31.10

| Firefox |
| :---: |
| port 1234) |
| Transport |
| Network |

## IP Packet Routing

- Each packet is individually routed

## IP Packet Routing

- Each packet is individually routed

## Packet Forwarding

- Packets are first stored before being forwarded - Why?

## Packet Forwarding Timing

- The queue has $Q$ bits when packet arrives $\rightarrow$ packet has to wait for the queue to drain before being transmitted

## Packet Forwarding Timing

## Packet Forwarding Timing

## Packet Forwarding Timing

## Packet Forwarding Timing: Packets of Different Lengths

## Datalink Layer

- Enable nodes (e.g., hosts, routers) connected by same link to exchange packets (frames) with each other
- Every node/interface has a datalink layer address (e.g., 6 bytes)
- No need to route packets, as each node on same link receives packets from everyone else on that link (e.g., WiFi, Ethernet)

IP address: 16.25.31.10
Datalink address: 111

## Datalink Layer

- Enable nodes (e.g., hosts, routers) connected by same link to exchange packets (frames) with each other
- Every node/interface has a datalink layer address (e.g., 6 bytes)
- Network layer picks the next router for the packet towards destination based on its destination IP address

Datalink address: 333

Datalink address: 222

## Physical Layer

- Move bits of information between two systems connected by a physical link
- Specifies how bits are represented (encoded), such as voltage level, bit duration, etc
- Examples: coaxial cable, optical fiber links; transmitters, receivers

## The Internet Hourglass

There is just one network-layer protocol, IP The "narrow waist" facilitates interoperability

## Implications of Hourglass \& Layering

Single Internet-layer module (IP):

- Allows arbitrary networks to interoperate
- Any network technology that supports IP can exchange packets
- Allows applications to function on all networks
- Applications that can run on IP can use any network technology
- Supports simultaneous innovations above and below IP
- But changing IP itself, i.e., IPv6, very involved

## TCP Open Connection: 3-Way Handshaking

- Goal: agree on a set of parameters: the start sequence number for each side
- Starting sequence numbers are random

## TCP Flow Control \& Reliability

- Sliding window protocol at byte (not packet) level
- Receiver tells sender how many more bytes it can receive without overflowing its buffer (i.e., AdvertisedWindow)
- Reliability
- The ack(nowledgement) contains sequence number N of next byte the receiver expects, i.e., receiver has received all bytes in sequence up to and including N-1
- Go-back-N: TCP Tahoe, Reno, New Reno
- Selective acknowledgement: TCP Sack
- We didn’t learn about congestion control (two lectures in ee122)

## Sliding Window

- window $=$ set of adjacent sequence numbers
- The size of the set is the window size
- Assume window size is n
- Let A be the last ack' d packet of sender without gap; then window of sender $=\{A+1, A+2, \ldots, A+n\}$
- Sender can send packets in its window
- Let $B$ be the last received packet without gap by receiver, then window of receiver $=\{B+1, \ldots, B+n\}$
- Receiver can accept out of sequence, if in window

## Go-Back-n (GBN)

- Transmit up to $n$ unacknowledged packets
- If timeout for $\operatorname{ACK}(k)$, retransmit $k, k+1, \ldots$

## GBN Example w/o Errors

Sender Window

## Window size $=3$ packets

Receiver Window

## GBN Example with Errors

## Observations

- With sliding windows, it is possible to fully utilize a link, provided the window size is large enough. Throughput is $\sim(n / R T T)$
- Stop \& Wait is like $\mathrm{n}=1$.
- Sender has to buffer all unacknowledged packets, because they may require retransmission
- Receiver may be able to accept out-of-order packets, but only up to its buffer limits

## Security

## How do You Secure your Credit Card?

- Use a secure protocol, e.g., HTTPS
- Need to ensure three properties:
- Confidentiality: an adversary cannot snoop the traffic
- Authentication: make sure you indeed talk with Amazon
- Integrity: an adversary cannot modify the message
" Used for improving authentication performance
- Cryptography based solution:
- General premise: there is a key, possession of which allows decoding, but without which decoding is infeasible
" Thus, key must be kept secret and not guessable

## Symmetric Keys

- Sender and receiver use the same key for encryption and decryption
- Examples: AES128, DES, 3DES

## Public Key / Asymmetric Encryption

- Sender uses receiver's public key
- Advertised to everyone
- Receiver uses complementary private key
- Must be kept secret
- Example: RSA

## Symmetric vs. Asymmetric Cryptography

- Symmetric cryptography
+Low overhead, fast
- Need a secret channel to distribute key
- Asymmetric cryptography
+No need for secret channel; public key known by everyone
+Provable secure
- Slow, large keys (e.g., 1024 bytes)

## Integrity

- Basic building block for integrity: hashing
- Associate hash with byte-stream, receiver verifies match
" Assures data hasn't been modified, either accidentally - or maliciously
- Approach:
- Sender computes a digest of message m, i.e., H(m)
" H() is a publicly known hash function
- Send digest $(d=H(m))$ to receiver in a secure way, e.g.,
" Using another physical channel
" Using encryption (e.g., Asymmetric Key)
- Upon receiving $m$ and d, receiver re-computes $H(m)$ to see whether result agrees with d
- Examples: MD5, SHA1

## Operation of Hashing for Integrity

## Digital Certificates

- How do you know $\mathbf{K}_{\text {Alice_pub }}$ is indeed Alice's public key?
- Main idea: trusted authority signing binding between Alice and its private key
- (offline) identity verification $\rightarrow$ VeriSign Authority

Alice, $\mathrm{K}_{\text {Alice_pub }}$

$$
\mathrm{E}\left(\left\{\text { Alice, } \mathrm{K}_{\text {Alice_pub }}\right\}, \mathrm{K}_{\text {verisign_private }}\right)
$$

$\mathrm{D}\left(\mathrm{E}\left(\left\{\right.\right.\right.$ Alice, $\left.\left.\left.\mathrm{K}_{\text {Alice_pub }}\right\}, \mathrm{K}_{\text {Verisign_private }}\right), \mathrm{K}_{\text {Verisign_public }}\right)=\left\{\right.$ Alice, $\left.\mathrm{K}_{\text {Alice_pub }}\right\}$

## HTTPS Connection (SSLTLS)

- Browser (client) connects via Browser

Amazon TCP to Amazon's HTTPS server

- Client sends over list of crypto protocols it supports
- Server picks protocols to use for this session
- Server sends over its certificate
- (all of this is in the clear)

## Inside the Server's Certificate

- Name associated with cert (e.g., Amazon)
- Amazon's RSA public key
- A bunch of auxiliary info (physical address, type of cert, expiration time)
- Name of certificate's signatory (who signed it)
- A public-key signature of a hash (SHA1) of all this
- Constructed using the signatory's private RSA key, i.e.,
- Cert $=E\left(H_{\text {SHA }}\left(K_{\text {public }}\right.\right.$, www.amazon.com, $\left.\left.\ldots\right), \mathrm{KS}_{\text {private }}\right)$
" $\mathrm{KA}_{\text {public: }}$ : Amazon's public key
" $\mathrm{KS}_{\text {private }}$ : signatory (certificate authority) public key

## Validating Amazon's Identity

- How does the browser authenticate certificate signatory?
- Certificates of few certificate authorities (e.g., Verisign) are hardwired into the browser
- If it can't find the cert, then warns the user that site has not been verified
- And may ask whether to continue
- Note, can still proceed, just without authentication
- Browser uses public key in signatory's cert to decrypt signature
- Compares with its own SHA1 hash of Amazon's cert
- Assuming signature matches, now have high confidence it's indeed Amazon ...
$-\ldots$ assuming signatory is trustworthy

## Certificate Validation

- You (browser) want to make sure that $\mathrm{KA}_{\text {public }}$ is indeed the public key of www.amazon.com

Certificate
$\mathrm{E}\left(\mathrm{H}_{\text {SHA1 } 1}\left(\mathrm{KA}_{\text {public }}, \underline{\text { www.amazon.com }}, \ldots\right), \mathrm{KS}_{\text {private }}\right)$,
www.amazon.com, KA ${ }_{\text {public }}, \mathrm{KS}_{\text {public }}, \ldots$

## HTTPS Connection (SSLTLS), con’t

- Browser constructs a random session (symmetric) key K
- Browser encrypts K using Amazon's public key
- Browser sends $\mathrm{E}\left(\mathrm{K}, \mathrm{KA}_{\text {public }}\right)$ to server
- Browser displays
- All subsequent communication encrypted w/ symmetric cipher (e.g., AES128) using key K
- E.g., client can authenticate using a password

Browser

## Two-Phase Locking (2PL)

## Concurrent Execution \& Transactions

- Concurrent execution essential for good performance
- Disk slow, so need to keep the CPU busy by working on several user programs concurrently
- DBMS only concerned about what data is read/written from/ to the database
- Not concerned about other operations performed by program on data
- Transaction - DBMS's abstract view of a user program, i.e., a sequence of reads and writes.

## Transaction - Example

BEGIN; --BEGIN TRANSACTION
UPDATE accounts SET balance = balance 100.00 WHERE name = 'Alice';

UPDATE branches SET balance = balance 100.00 WHERE name $=$ (SELECT branch_name FROM accounts WHERE name = 'Alice');

UPDATE accounts SET balance = balance + 100.00 WHERE name = 'Bob';

UPDATE branches SET balance = balance + 100.00 WHERE name = (SELECT branch_name FROM accounts WHERE name = 'Bob');

COMMIT; --COMMIT WORK

## The ACID properties of Transactions

- Atomicity: all actions in the transaction happen, or none happen
- Consistency: if each transaction is consistent, and the DB starts consistent, it ends up consistent
- Isolation: execution of one transaction is isolated from that of all others
- Durability: if a transaction commits, its effects persist

## Transaction Scheduling

- Serial schedule: A schedule that does not interleave the operations of different transactions
- Transactions run serially (one at a time)
- Equivalent schedules: For any database state, the effect (on the database) and output of executing the first schedule is identical to the effect of executing the second schedule
- Serializable schedule: A schedule that is equivalent to some serial execution of the transactions
- Intuitively: with a serializable schedule you only see things that could happen in situations where you were running transactions one-at-a-time.

## Conflict Serializable Schedules

- Two operations conflict if they
- Belong to different transactions
- Are on the same data
- At least one of them is a write.
- Two schedules are conflict equivalent iff:
- Involve same operations of same transactions
- Every pair of conflicting operations is ordered the same way
- Schedule $S$ is conflict serializable if $S$ is conflict equivalent to some serial schedule

## Conflict Equivalence - Intuition

- If you can transform an interleaved schedule by swapping consecutive non-conflicting operations of different transactions into a serial schedule, then the original schedule is conflict serializable
- Example:

## Conflict Equivalence - Intuition (cont'd)

- If you can transform an interleaved schedule by swapping consecutive non-conflicting operations of different transactions into a serial schedule, then the original schedule is conflict serializable
- Example:

| T1:R(A), W (A) , R ( $\mathrm{B}^{\text {) }}$ |  | W (B) |
| :---: | :---: | :---: |
| T2: | $\mathrm{R}(\mathrm{A}), \mathrm{W}(\mathrm{A})$ | R (B) , W (B) |
| V |  |  |
| T1: $\mathrm{R}(\mathrm{A}), \mathrm{W}(\mathrm{A}), \mathrm{R}(\mathrm{B}), \quad \mathrm{W}(\mathrm{B})$ |  |  |
| T2: | R(A), | $W(A), R(B), W(B)$ |
| V |  |  |
|  |  |  |
| T2: | R(A), | $W(A), R(B), W(B)$ |

## Conflict Equivalence - Intuition (cont'd)

- If you can transform an interleaved schedule by swapping consecutive non-conflicting operations of different transactions into a serial schedule, then the original schedule is conflict serializable
- Is this schedule serializable?

$$
\begin{aligned}
& \mathrm{T} 1: \mathrm{R}(\mathrm{~A}), \quad \mathrm{W}(\mathrm{~A}) \\
& \mathrm{T} 2: \quad \mathrm{R}(\mathrm{~A}), \mathrm{W}(\mathrm{~A}),
\end{aligned}
$$

## Dependency Graph

- Dependency graph:
- Transactions represented as nodes
- Edge from Ti to Tj:
" an operation of Ti conflicts with an operation of Tj
» Ti appears earlier than $\mathrm{Tj}_{\mathrm{j}}$ in the schedule
- Theorem: Schedule is conflict serializable if and only if its dependency graph is acyclic

## Example

- Conflict serializable schedule:

```
T1:R(A),W(A), R(B),W(B)
T2:
R(A),W(A),
R(B),W(B)
```

Dependency graph

- No cycle!

## Example

- Conflict that is not serializable:

```
T1:R(A),W(A),
R(B),W(B)
T2: R(A),W(A),R(B),W(B)
```

## Dependency graph

- Cycle: The output of T1 depends on T2, and viceversa

## Notes on Conflict Serializability

- Conflict Serializability doesn't allow all schedules that you would consider correct
- This is because it is strictly syntactic - it doesn't consider the meanings of the operations or the data
- In practice, Conflict Serializability is what gets used, because it can be done efficiently
- Note: in order to allow more concurrency, some special cases do get implemented, such as for travel reservations, ...
- Two-phase locking (2PL) is how we implement it

## Locks

- "Locks" to control access to data
- Two types of locks:
- shared (S) lock - multiple concurrent transactions allowed to operate on data
- exclusive (X) lock - only one transaction can operate on data at a time

## Lock <br> Compatibility Matrix

## Two-Phase Locking (2PL)

1) Each transaction must obtain:

- S (shared) or X (exclusive) lock on data before reading,
- X (exclusive) lock on data before writing

2) A transaction can not request additional locks once it releases any locks.
Thus, each transaction has a "growing phase" followed by a "shrinking phase" Lock Point!

## Two-Phase Locking (2PL)

- 2PL guarantees conflict serializability
- Doesn't allow dependency cycles; Why?
- Answer: a cyclic dependency cycle leads to deadlock
- Edge from Ti to Tj means that Ti acquires lock first and Tj needs to wait
- Edge from Ti to Tj means that Ti acquires lock first and Tj needs to wait
- Thus, both T1 and Tj wait for each other $\rightarrow$ deadlock
- Schedule of conflicting transactions is conflict equivalent to a serial schedule ordered by "lock point"

## Deadlock Prevention

- Assign priorities based on timestamps. Assume Ti wants a lock that Tj holds. Two policies are possible:
- Wait-Die: If Ti is older, Ti waits for Tj; otherwise Ti aborts
- Wound-wait: If Ti is older, Tj aborts; otherwise Ti waits
- If a transaction re-starts, make sure it gets its original timestamp
- Why?

## Example

- T1 transfers $\$ 50$ from account $A$ to account B

T1: Read (A), A:=A-50,Write (A), Read (B) , B: $=\mathrm{B}+50$, Write (B)

- T2 outputs the total of accounts $A$ and $B$

T2: Read (A) , Read (B) , PRINT (A+B)

- Initially, $A=\$ 1000$ and $B=\$ 2000$
- What are the possible output values?

## Is this a 2PL Schedule?

| Lock_X(A) <granted> |  |
| :--- | :--- |
| Read(A) | Lock_S(A) |
| A: = A-50 |  |
| Write(A) |  |
| Unlock(A) | Read(A) |
|  | Unlock(A) |
|  | Lock_S(B) <granted > $>$ |
|  |  |
| Lock_X(B) | Read(B) |
|  | Unlock(B) |
| $\downarrow$ <granted> | PRINT(A+B) |
| Read(B) |  |
| B := B +50 |  |
| Write(B) |  |
| Unlock(B) |  |

No, and it is not serializable

## Is this a 2PL Schedule?

| Lock_X(A) <granted> |  |
| :---: | :---: |
| Read(A) | Lock_S(A) |
| A: $=$ A-50 |  |
| Write(A) |  |
| Lock_X(B) <granted> |  |
| Unlock(A) | $\downarrow$ <granted> |
|  | Read(A) |
|  | Lock_S(B) |
| Read(B) |  |
| B : = B +50 |  |
| Write(B) |  |
| Unlock(B) | $\downarrow$ <granted> |
|  | Unlock(A) |
|  | Read(B) |
|  | Unlock(B) |
|  | PRINT(A+B) |

## Yes, so it is serializable

## Cascading Aborts

- Example: T1 aborts
- Note: this is a 2PL schedule

```
T1:R(A),W(A), R(B),W(B), Abort
T2:
R(A),W(A)
```

- Rollback of T1 requires rollback of T2, since T2 reads a value written by T1
- Solution: Strict Two-phase Locking (Strict 2PL): same as 2PL except
- All locks held by a transaction are released only when the transaction completes

## Strict 2PL (cont'd)

- All locks held by a transaction are released only when the transaction completes
- In effect, "shrinking phase" is delayed until:
a) Transaction has committed (commit log record on disk), or
b) Decision has been made to abort the transaction (then locks can be released after rollback).

## Is this a Strict 2PL schedule?

| Lock_X(A) <granted> |  |  |
| :--- | :--- | :---: |
| Read(A) | Lock_S(A) |  |
| A: =A-50 |  |  |
|  |  |  |
| Write(A) |  |  |
|  |  |  |
| Lock_X(B) <granted> |  |  |
| Unlock(A) | $\downarrow$ |  |
|  | Read(A) |  |
|  | Lock_S(Branted> |  |
| Read(B) |  |  |
| B := B +50 |  |  |
| Write(B) |  |  |
| Unlock(B) | $\downarrow$ |  |
|  | Unlock(A) |  |
|  | Read(B) |  |
|  | Unlock(B) |  |
|  | PRINT(A+B) |  |

## Is this a Strict 2PL schedule?

| Lock_X(A) <granted> |  |  |
| :--- | :--- | :---: |
| Read(A) | Lock_S(A) |  |
| A: = A-50 |  |  |
|  |  |  |
| Write(A) |  |  |
|  |  |  |
| Lock_X(B) <granted> |  |  |
|  |  |  |
| Read(B) |  |  |
|  |  |  |
| B := B +50 |  |  |
| Write(B) |  |  |
| Unlock(A) |  |  |
| Unlock(B) | Read(A) |  |
|  | Lock_S(B) <granted> |  |
|  | Read(B) |  |
|  | PRINT(A+B) |  |
|  | Unlock(A) |  |
|  | Unlock(B) |  |

## Two-Phase Commit (2PC)

## Two Phase (2PC) Commit

- 2PC is a distributed protocol
- High-level problem statement
- If no node fails and all nodes are ready to commit, then all nodes COMMIT
- Otherwise ABORT at all nodes
- Developed by Turing award winner Jim Gray (first Berkeley CS PhD, 1969)

## Detailed Algorithm

## Coordinator Algorithm

Coordinator sends VOTE-REQ to all workers

## Worker Algorithm

- Wait for VOTE-REQ from coordinator
- If ready, send VOTE-COMMIT to coordinator
- If not ready, send VOTE-ABORT to coordinator
- And immediately abort all workers
- If doesn't receive VOTE-COMMIT from all N workers, send GLOBALABORT to all workers
- If receive GLOBAL-COMMIT then commit
- If receive GLOBAL-ABORT then abort

## Failure Free Example Execution

## State Machine of Coordinator

- Coordinator implements simple state machine

## State Machine of workers

## Dealing with Worker Failures

- How to deal with worker failures?
- Failure only affects states in which the node is waiting for messages
- Coordinator only waits for votes in "WAIT" state
- In WAIT, if doesn't receive N votes, it times out and sends GLOBAL-ABORT

Recv: VOTE-ABORT Send: GLOBAL-ABORT ABORT

Recv: VOTE-COMMIT
Send: GLOBAL-COMMIT COMMIT

## Dealing with Coordinator Failure

- How to deal with coordinator failures?
- worker waits for VOTE-REQ in INIT
" Worker can time out and abort (coordinator handles it)
- worker waits for GLOBAL-* message in READY
" If coordinator fails, workers must BLOCK waiting for coordinator to recover and send GLOBAL_* message

## Example of Coordinator Failure \#1

## Example of Coordinator Failure \#2

## Remembering Where We Were

- All nodes use stable storage to store which state they were in
- Upon recovery, it can restore state and resume:
- Coordinator aborts in INIT, WAIT, or ABORT
- Coordinator commits in COMMIT
- Worker aborts in INIT, READY, ABORT
- Worker commits in COMMIT

## Blocking for Coordinator to Recover

- A worker waiting for global decision can ask fellow workers about their state
- If another worker is in ABORT or COMMIT state then coordinator must INIT have sent GLOBAL-*
- Thus, worker can safely abort or commit, respectively
- If another worker is still in INIT state then both workers can decide to abort ABORT

COMMIT

- If all workers are in ready, need to BLOCK (don't know if coordinator wanted to abort or commit)
