Lecture #31: Code Generation		Intermediate Languages and Machine Languages	
[This lecture adopted in part from notes by R. Bodik]		 From trees such as output from project #2, could produce machine language directly. 	e
		 However, it is often convenient to first generate some kind of inter- mediate language (IL): a "high-level machine language" for a "virtua machine." 	
		• Advantages:	
		 Separates problem of extracting the operational meaning (the dynamic semantics) of a program from the problem of producing good machine code from it, because it 	
		 Gives a clean target for code generation from the AST. 	
		 By choosing IL judiciously, we can make the conversion of IL — machine language easier than the direct conversion of AST → machine language. Helpful when we want to target several different architectures (e.g., gcc). 	l-
		– Likewise, if we can use the same IL for multiple languages, we can re-use the IL $ ightarrow$ machine language implementation (e.g., gcc, CIL from Microsoft's Common Language Infrastructure).

Translating from AST to Stack Machine	Virtual Register Machines and Three-Address Code	
 A simple recursive pattern usually serves for expressions. At the top level, our trees might have an expression-code me class AST { 	• Another common kind of virtual machine has an infinite supply of registers, each capable of holding a scalar value or address, in add tion to ordinary memory.	
<pre> /** Generate code for me, leaving my value on the stack.</pre>	 A common IL in this case is some form of three-address code, s called because the typical "working" instruction has the form 	50
<pre>virtual void cgen (VM* machine); }</pre>	$\textsf{target} \mathrel{\mathop:}= \textsf{operand}_1 \oplus \textsf{operand}_2$	
 Implementations of cgen then obey this general comment, an assumes that its children will as well. E.g., 	each where there are two source "addresses," one destination "addresses" and an operation (\oplus) .	s"
<pre>class BinopNode : public AST { void cgen (VM* machine) { getRight ()->cgen (machine); getLeft ()->cgen (machine); machine->emitInst (translateToInst (getOp ())); } }</pre>	 Often, we require that the operands in the full three-address for denote (virtual) registers or immediate (literal) values. 	'n
We assume here a VM is some abstraction of the virtual m we're producing code for. emitInst adds machine instruct the program, and translateToInst converts, e.g., a '+' to add Last modified: Fri Apr 8 01:15:37 2011 CS164: Lec	s to	. 8

Three-Address Code, continued

A Larger Example

Consider a small language with integers and integer operations:

```
P:
      D ";" P | D
D:
      "def" id(ARGS) "=" E;
ARGS: id "," ARGS | id
E:
      int | id | "if" E1 "=" E2 "then" E3 "else" E4 "fi"
          | E1 "+" E2 | E1 "-" E2 | id "(" E1,...,En ")"
```

- The first function definition f is the "main" routine
- Running the program on input i means computing f(i)
- Assume a project-2-like AST.
- Let's continue implementing cgen ('+' and '-' already done).

Simple Cases: Literals and Sequences

Translating from AST into Three-Address Code

```
Conversion of D ";" P:
  class StmtListNode : public AST {
     Operand* cgen (VM* machine) {
        for (int i = 0; i < arity (); i += 1)
           get (i)->cgen (machine);
     }
     return Operand::NoneOperand;
  }
  class IntLiteralNode : public AST {
     Operand* cgen (VM* machine) {
         return machine->immediateOperand (intTokenValue ());
     }
  }
```

• NoneOperand is an Operand that contains None.

Identifiers

```
class IdNode : public AST {
                                                                                              class CallNode : public AST {
     . . .
                                                                                                 . . .
     Operand* cgen (VM* machine) {
                                                                                                 Operand* cgen (VM* machine) {
        Operand result = machine->allocateRegister ();
                                                                                                    AST* args = getArgList ();
        machine->emitInst (MOVE, result, getDecl()->getMyLocation (machine));
                                                                                                    for (int i = args->arity ()-1; i >= 0; i -= 1)
        return result;
                                                                                                        machine->emitInst (PARAM, args.get (i)->cgen (machine));
     }
                                                                                                    Operand* callable = getCallable ()->cgen (machine);
  }
                                                                                                    machine->emitInst (CALL, callable, args->arity ());
                                                                                                    return Operand::ReturnOperand;
 • That is, we assume that the declaration object holding information
                                                                                                 }
   about this occurrence of the identifier contains its location.
                                                                                              }
                                                                                             • ReturnOperand is abstract location where functions return their
                                                                                               value.
