CS162 Operating Systems and Systems Programming Lecture 21

Networking

November 14, 2007 Prof. John Kubiatowicz http://inst.eecs.berkeley.edu/~cs162

Review: File System Caching

 Delayed Writes: Writes to files not immediately sent out to disk 			
 Instead, write() copies data from user space buffer to kernel buffer (in cache) 			
» Enabled by presence of buffer cache: can leave written file blocks in cache for a while			
» If some other application tries to read data before written to disk, file system will read from cache			
- Flushed to disk periodically (e.g. in UNIX, every 30 sec)			
- Advantages:			
 » Disk scheduler can efficiently order lots of requests » Disk allocation algorithm can be run with correct size value for a file 			
» Some files need never get written to disk! (eg temporary scratch files written /tmp often don't exist for 30 sec)			
- Disadvantages			
 What if system crashes before file has been written out? Worse yet, what if system crashes before a directory file has been written out? (lose pointer to inode!) 			
11/14/07 Kubiatowicz CS162 ©UCB Fall 2007 Lec 21.2			

Review: RAID 5+: High I/O Rate Parity

Data stripped across					= Stripe Unit	
multiple disks	ро	D1	D2			
- Successive blocks		DI	02	D3	PO	
stored on successive						Increasing
(non-parity) disks	D4	D5	D6	P1	D7	Logical Disk
- Increased bandwidth						Addresses
over single disk	D8	D9	P2	D10	D11	1 1
Parity block (in green)						
constructed by XORing	D12	P3	D13	D14	D15	
data bocks in stripe						
- P0=D0⊕D1⊕D2⊕D3	P4	D16	D17	D18	D19	•
- Can destroy any one					017	
disk and still	D20	D21	D22	D23	0.E	
reconstruct data	020	021	022	023	P5	
- Suppose D3 fails, then can reconstruct:	Disk 1	Disk 2	Disk 3	Disk 4	Disk 5	
D3=D0⊕D1⊕D2⊕P0						

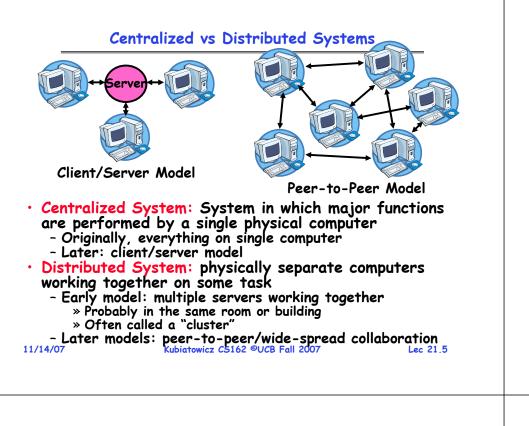

• Later in term: talk about spreading information widely across internet for durability.

Lec 21.3

Goals for Today

- Networking
 - Broadcast
 - Point-to-Point Networking
 - Routing
 - Internet Protocol (IP)

Note: Some slides and/or pictures in the following are adapted from slides ©2005 Silberschatz, Galvin, and Gagne. Many slides generated from my lecture notes by Kubiatowicz.

Distributed Systems: Motivation/Issues

- Why do we want distributed systems?
 - Cheaper and easier to build lots of simple computers
 - Easier to add power incrementally
 - Users can have complete control over some components
 - Collaboration: Much easier for users to collaborate through network resources (such as network file systems)
- The *promise* of distributed systems:
 - Higher availability: one machine goes down, use another
 - Better durability: store data in multiple locations
 - More security: each piece easier to make secure
- Reality has been disappointing

 Worse availability: depend on every machine being up
 Lamport: "a distributed system is one where I can't do work because some machine I've never heard of isn't working!"
 - Worse reliability: can lose data if any machine crashes
 - Worse security: anyone in world can break into system
- Coordination is more difficult
 - Must coordinate multiple copies of shared state information (using only a network)
 - What would be easy in a centralized system becomes a lot more difficult

```

```

Kubiatowicz CS162 ©UCB Fall 2007

Lec 21.6

Distributed Systems: Goals/Requirements

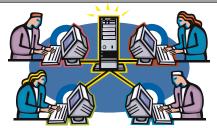

- Transparency: the ability of the system to mask its complexity behind a simple interface
- Possible transparencies:
 - Location: Can't tell where resources are located
 - Migration: Resources may move without the user knowing
 - Replication: Can't tell how many copies of resource exist
 - Concurrency: Can't tell how many users there are
 - Parallelism: System may speed up large jobs by spliting them into smaller pieces
 - Fault Tolerance: System may hide varoius things that go wrong in the system
- Transparency and collaboration require some way for different processors to communicate with one another

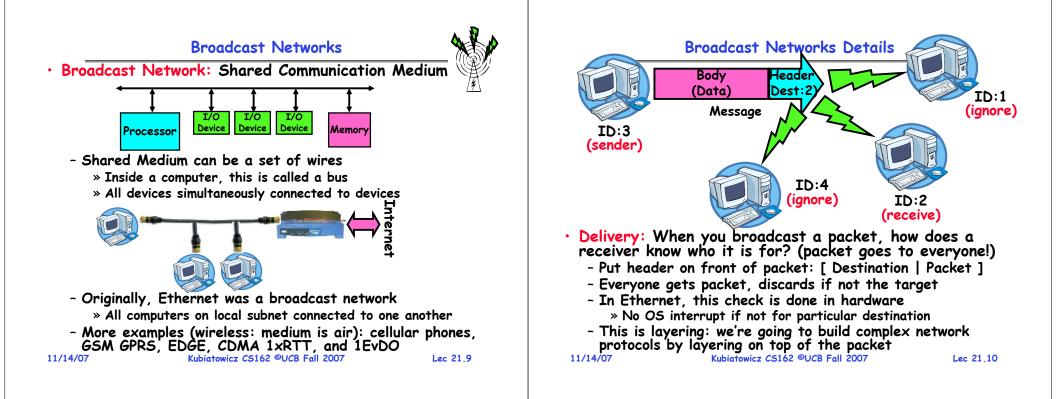

11/14/07

Lec 21.7

Networking Definitions

- Network: physical connection that allows two computers to communicate
- Packet: unit of transfer, sequence of bits carried over the network
 - Network carries packets from one CPU to another
 - Destination gets interrupt when packet arrives
- Protocol: agreement between two parties as to how information is to be transmitted

Broadcast Network Arbitration

- · Arbitration: Act of negotiating use of shared medium
 - What if two senders try to broadcast at same time?
 - Concurrent activity but can't use shared memory to coordinate!
- Aloha network (70's): packet radio within Hawaii
 - Blind broadcast, with checksum at end of packet. If received correctly (not garbled), send back an acknowledgement. If not received correctly, discard.

- » Need checksum anyway in case airplane flies overhead
- Sender waits for a while, and if doesn't get an acknowledgement, re-transmits.
- If two senders try to send at same time, both get garbled, both simply re-send later.
- Problem: Stability: what if load increases?
 - » More collisions \Rightarrow less gets through \Rightarrow more resent \Rightarrow more $load... \Rightarrow More collisions...$
 - » Unfortunately: some sender may have started in clear, get scrambled without finishing

Carrier Sense, Multiple Access/Collision Detection

- Ethernet (early 80's): first practical local area network
 - It is the most common LAN for UNIX, PC, and Mac - Use wire instead of radio, but still broadcast medium
- Key advance was in arbitration called CSMA/CD: Carrier sense, multiple access/collision detection
 - Carrier Sense: don't send unless idle
 - » Don't mess up communications already in process
 - Collision Detect: sender checks if packet trampled. » If so, abort, wait, and retry.
 - Backoff Scheme: Choose wait time before trying again
- How long to wait after trying to send and failing?
 What if everyone waits the same length of time? Then,
 - they all collide again at some time!
 - Must find way to break up shared behavior with nothing more than shared communication channel
- Adaptive randomized waiting strategy:
 - Adaptive and Random: First time, pick random wait time with some initial mean. If collide again, pick random value from bigger mean wait time. Etc.
 - Randomness is important to decouple colliding senders
- Scheme figures out how many people are trying to send! Kubiatowicz CS162 ©UCB Fall 2007 11/14/07 Lec 21,12

Administrivia

• Exam reminders:

- MIDTERM II: Wednesday Dec 5th
 - » All material from last midterm and up to Monday 12/3 » Lectures #12 - 26
- Final Exam
 - » Sat Dec 17th, 5:00-8:00pm
 - » All Material
- Project 3 due tomorrow at midnight

Lec 21.13

Point-to-Point Networks Discussion

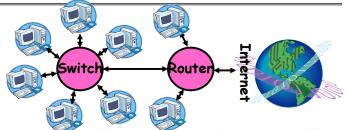

Advantages:

- Higher link performance
 - » Can drive point-to-point link faster than broadcast link since less capacitance/less echoes (from impedance mismatches)
- Greater aggregate bandwidth than broadcast link » Can have multiple senders at once
- Can add capacity incrementally
 - » Add more links/switches to get more capacity
- Better fault tolerance (as in the Internet)
- Lower Latency
- » No arbitration to send, although need buffer in the switch
- Disadvantages:
 - More expensive than having everyone share broadcast link
 - However, technology costs now much cheaper
- Examples
 - ATM (asynchronous transfer mode)
 - » The first commercial point-to-point LAN
 - » Inspiration taken from telephone network
 - Switched Ethernet
 - » Same packet format and signaling as broadcast Ethernet, but only two machines on each ethernet. Lec 21,15

11/14/07

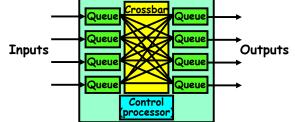

Kubiatowicz CS162 ©UCB Fall 2007

Point-to-point networks

- Why have a shared bus at all? Why not simplify and only have point-to-point links + routers/switches?
 - Didn't used to be cost-effective
 - Now, easy to make high-speed switches and routers that can forward packets from a sender to a receiver.
- · Point-to-point network: a network in which every physical wire is connected to only two computers
- Switch: a bridge that transforms a shared-bus (broadcast) configuration into a point-to-point network.
- Router: a device that acts as a junction between two
- networks to transfer data packets among them. Kubiatowicz C5162 ©UCB Fall 2007 11/14/07

Point-to-Point Network design

- Switches look like computers: inputs, memory, outputs - In fact probably contains a processor
- Function of switch is to forward packet to output that gets it closer to destination
- Can build big crossbar by combining smaller switches

 Can perform broadcast if necessary 11/14/07 Kubiatowicz CS162 ©UCB Fall 2007

Lec 21,16

Lec 21.14

Flow control options

- What if everyone sends to the same output? - Congestion—packets don't flow at full rate
- In general, what if buffers fill up?
 - Need flow control policy
- Option 1: no flow control. Packets get dropped if they arrive and there's no space
 - If someone sends a lot, they are given buffers and packets from other senders are dropped
 - Internet actually works this way
- Option 2: Flow control between switches
 - When buffer fills, stop inflow of packets
 - Problem: what if path from source to destination is completely unused, but goes through some switch that has buffers filled up with unrelated traffic? Lec 21.17

11/	14/	07

```
Kubiatowicz CS162 ©UCB Fall 2007
```

Flow Control (con't)

- Option 3: Per-flow flow control.
 - Allocate a separate set of buffers to each end-toend stream and use separate "don't send me more" control on each end-to-end stream

- Problem: fairness
 - Throughput of each stream is entirely dependent on topology, and relationship to bottleneck
- · Automobile Analogy
 - At traffic jam, one strategy is merge closest to the bottleneck
 - » Why people get off at one exit, drive 50 feet, merge back into flow
 - » Ends up slowing everybody else a huge emount
 - Also why have control lights at on-ramps
 - » Try to keep from injecting more cars than capacity of road (and thus avoid congestion) Kubiatowicz CS162 ©UCB Fall 2007 Lec 21.18

11/14/07

11/14/07

- The Internet is a large network of computers spread across the globe
 - According to the Internet Systems Consortium, there were over 353 million computers as of July 2005

The Internet Protocol: "IP"

- In principle, every host can speak with every other one under the right circumstances
- IP Packet: a network packet on the internet
- IP Address: a 32-bit integer used as the destination of an IP packet
 - Often written as four dot-separated integers, with each integer from 0-255 (thus representing $8\times4=32$ bits) - Example CS file server is: 169.229.60.83 = 0xA9E53C53
- Internet Host: a computer connected to the Internet - Host has one or more IP addresses used for routing » Some of these may be private and unavailable for routing
 - Not every computer has a unique IP address
 - » Groups of machines may share a single IP address
 - » In this case, machines have private addresses behind a "Network Address Translation" (NAT) gateway

Address Subnets

- Subnet: A network connecting a set of hosts with related destination addresses
- With IP, all the addresses in subnet are related by a prefix of bits
 - Mask: The number of matching prefix bits » Expressed as a single value (e.g., 24) or a set of ones in a 32-bit value (e.g., 255.255.255.0)
- A subnet is identified by 32-bit value, with the bits which differ set to zero, followed by a slash and a mask
 - Example: 128.32.131.0/24 designates a subnet in which all the addresses look like 128, 32, 131, XX
 - Same subnet: 128.32.131.0/255.255.255.0
- Difference between subnet and complete network range
 - Subnet is always a subset of address range
 - Once, subnet meant single physical broadcast wire; now, less clear exactly what it means (virtualized by switches)

- Address Ranges in IP • IP address space divided into prefix-delimited ranges: - Class A: NN.0.0.0/8 » NN is 1-126 (126 of these networks) » 16,777,214 IP addresses per network » 10.xx.yy.zz is private » 127.xx.yy.zz is loopback - Class B: NN.MM.0.0/16 » NN is 128-191, MM is 0-255 (16,384 of these networks) » 65,534 IP addresses per network » 172.[16-31].xx.yy are private - Class C: NN.MM.LL.0/24 » NN is 192–223. MM and LL 0–255 (2,097,151 of these networks) » 254 IP addresses per networks » 192.168.xx.yy are private
- Address ranges are often owned by organizations
 - Can be further divided into subnets

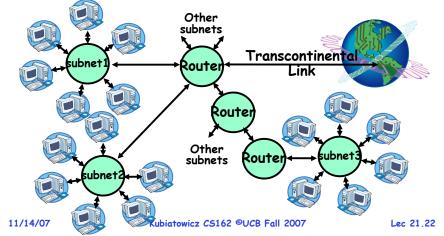

```
11/14/07
```

Kubiatowicz CS162 ©UCB Fall 2007

Lec 21,21

Hierarchical Networking: The Internet

- How can we build a network with millions of hosts? - Hierarchy! Not every host connected to every other one - Use a network of Routers to connect subnets together
 - » Routing is often by prefix: e.g. first router matches first 8 bits of address, next router matches more, etc.

Simple Network Terminology

- · Local-Area Network (LAN) designed to cover small geographical area
 - Multi-access bus, ring, or star network
 - Speed ≈ 10 1000 Megabits/second
 - Broadcast is fast and cheap
 - In small organization, a LAN could consist of a single subnet. In large organizations (like UC Berkeley), a LAN contains many subnets
- Wide-Area Network (WAN) links geographically separated sites
 - Point-to-point connections over long-haul lines (often leased from a phone company)
 - Speed ≈ 1.544 45 Megabits/second
 - Broadcast usually requires multiple messages

Routing

- · Routing: the process of forwarding packets hop-by-hop through routers to reach their destination
 - Need more than just a destination address! » Need a path
 - Post Office Analogy:

- » Destination address on each letter is not sufficient to get it to the destination
- » To get a letter from here to Florida, must route to local post office, sorted and sent on plane to somewhere in Florida, be routed to post office, sorted and sent with carrier who knows where street and house is...
- Internet routing mechanism: routing tables
 - Each router does table lookup to decide which link to use to get packet closer to destination
 - Don't need 4 billion entries in table: routing is by subnet
 - Could packets be sent in a loop? Yes, if tables incorrect
- Routing table contains:
 - Destination address range \rightarrow output link closer to destination
 - Default entry (for subnets without explicit entries) Kubiatowicz CS162 ©UCB Fall 2007

Lec 21,23

Setting up Routing Tables

- How do you set up routing tables?
 - Internet has no centralized state!
 - $\ensuremath{\mathbin{\text{\circle*{1.5}}}}$ No single machine knows entire topology
 - » Topology constantly changing (faults, reconfiguration, etc)
 - Need dynamic algorithm that acquires routing tables
 - » Ideally, have one entry per subnet or portion of address
 - » Could have "default" routes that send packets for unknown subnets to a different router that has more information
- $\boldsymbol{\cdot}$ Possible algorithm for acquiring routing table
 - Routing table has "cost" for each entry
 - » Includes number of hops to destination, congestion, etc.
 - » Entries for unknown subnets have infinite cost
 - Neighbors periodically exchange routing tables
 - » If neighbor knows cheaper route to a subnet, replace your entry with neighbors entry (+1 for hop to neighbor)

Lec 21.25

• In reality:

11/14/07

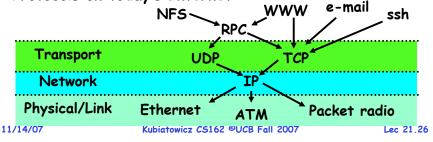

- Internet has networks of many different scales

- Different	algorithms run at different scales	
11/14/07	Kubiatowicz CS162 ©UCB Fall 2007	

```
Network Protocols
```

- Networking examples: many levels
 - » Physical level: mechanical and electrical network (e.g. how are 0 and 1 represented)
 - » Link level: packet formats/error control (for instance, the CSMA/CD protocol)
 - » Network level: network routing, addressing
 - » Transport Level: reliable message delivery
- Protocols on today's Internet:

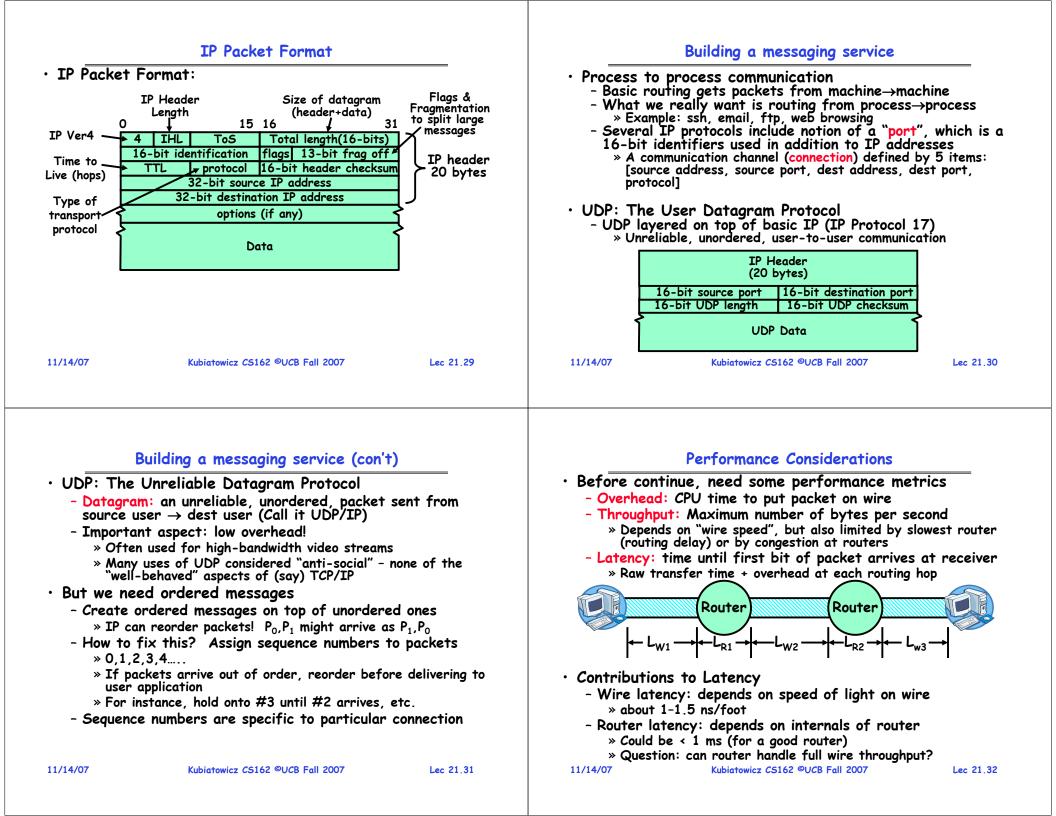

Network Layering

- · Layering: building complex services from simpler ones
 - Each layer provides services needed by higher layers by utilizing services provided by lower layers
- \cdot The physical/link layer is pretty limited
 - Packets are of limited size (called the "Maximum Transfer Unit or MTU: often 200-1500 bytes in size)
 - Routing is limited to within a physical link (wire) or perhaps through a switch
- Our goal in the following is to show how to construct a secure, ordered, message service routed to anywhere:

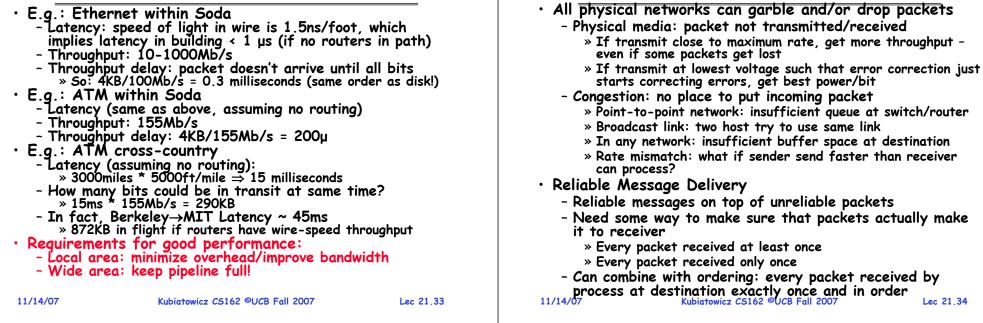

· · · · · ·		
Physical Reality: Packets	Abstraction: Messages	
Limited Size	Arbitrary Size	1
Unordered (sometimes)	Ordered	1
Unreliable	Reliable	
Machine-to-machine	Process-to-process	
Only on local area net	Routed anywhere	
Asynchronous	Synchronous	1
Insecure	Secure	Lec 21.27

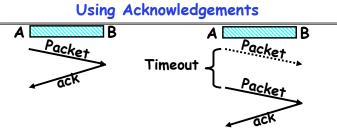

Building a messaging service

- Handling Arbitrary Sized Messages:
 - Must deal with limited physical packet size
 - Split big message into smaller ones (called fragments) » Must be reassembled at destination
 - Checksum computed on each fragment or whole message
- Internet Protocol (IP): Must find way to send packets to arbitrary destination in network
 - Deliver messages unreliably ("best effort") from one machine in Internet to another
 - Since intermediate links may have limited size, must be able to fragment/reassemble packets on demand
 - Includes 256 different "sub-protocols" build on top of IP » Examples: ICMP(1), TCP(6), UDP (17), IPSEC(50,51)

Sample Computations

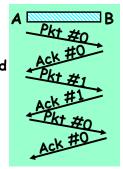

- How to ensure transmission of packets?
 - Detect garbling at receiver via checksum, discard if bad
 - Receiver acknowledges (by sending "ack") when packet received properly at destination
 - Timeout at sender: if no ack, retransmit
- Some questions:
 - If the sender doesn't get an ack, does that mean the receiver didn't get the original message?
 » No
 - What it ack gets dropped? Or if message gets delayed?
 » Sender doesn't get ack, retransmits. Receiver gets message twice, acks each.

Lec 21.35

How to deal with message duplication

Reliable Message Delivery: the Problem

- Solution: put sequence number in message to identify re-transmitted packets
 - Receiver checks for duplicate #'s; Discard if detected
- Requirements:
 - Sender keeps copy of unack'ed messages » Easy: only need to buffer messages
 - Receiver tracks possible duplicate messages
 » Hard: when ok to forget about received message?
- Simple solution: Alternating-bit protocol
 - Send one message at a time; don't send next message until ack received
 - Sender keeps last message; receiver tracks sequence # of last message received
- Pros: simple, small overhead
- Con: Poor performance
 - Wire can hold multiple messages; want to fill up at (wire latency × throughput)
- Con: doesn't work if network can delay or duplicate messages arbitrarily 11/14/07
 Kubiatowicz C5162 @UCB Fall 2007

Lec 21.36

Conclusion

- Network: physical connection that allows two computers to communicate
 - Packet: sequence of bits carried over the network
- Broadcast Network: Shared Communication Medium
 Transmitted packets sent to all receivers
 - Arbitration: act of negotiating use of shared medium » Ethernet: Carrier Sense, Multiple Access, Collision Detect
- Point-to-point network: a network in which every physical wire is connected to only two computers
 - Switch: a bridge that transforms a shared-bus (broadcast) configuration into a point-to-point network.
- Protocol: Agreement between two parties as to how information is to be transmitted
- Internet Protocol (IP)
 - Used to route messages through routes across globe
 - 32-bit addresses, 16-bit ports
- Reliable, Ordered, Arbitrary-sized Messaging:
 - Built through protocol layering on top of unreliable, limited-sized, non-ordered packet transmission links

11/14/07	Kubiatowicz CS162 ©UCB Fall 2007	Lec 21.37
