CS168 Fall 2014
Homework 1
Assigned: Wednesday, 10 September 2014
Due: Monday, 22 September 2014

Name: ____________________________

SID: ____________________________

Discussion Section (Day/Time): ____________________________

Instructions

- Submit this homework using Pandagrader/GradeScope (https://www.gradescope.com/courses/214).

- To submit, print out this document, write your answers on it, then scan it and upload to Pandagrader. Scanning services are available from the Berkeley Library System (http://www.lib.berkeley.edu/using-the-libraries/print-scan). Be sure to double-check your submission to ensure that Pandagrader has scanned in your solution correctly. You may want to consider using a pdf markup program to insert your answers into this document in the provided spaces, especially in Problem 5 if your plot is computer-generated.

- Use your @berkeley.edu email address to sign in to Pandagrader. If you don’t have a Pandagrader account, click ”Login” and then ”Forgot Password” on the Pandagrader website and follow the instructions. If you have any problems with the submission process, it is your responsibility to come to office hours prior to the homework’s due date.

- If you need more space for work, or you write code to calculate a result, attach these materials at the end of the homework when you submit.

- If you have questions, ask on Piazza (strongly preferred) or email Akshay (akshay [dot] narayan [at] berkeley).

- Some potentially useful information:
  1. Byte = 8 bits, 1 Mbps = 10^6 bits/sec, 1 Gbps = 10^9 bits/sec, 1 ms = 10^-3 sec.
1. (20 points) **Miscellaneous Short Questions**

(a) (4 points) Consider a single link with bandwidth \( B \) and propagation delay (i.e., latency) \( L \). It takes 1ms for an entire 500 byte packet to arrive at other end of the link (that is, it takes 1ms from the time the first bit starts being transmitted until the last bit arrives at the other end of the link). It takes 2ms for an entire 1500 byte packet to arrive at the other end of the link.

(i) What is the bandwidth \( B \) of the link? (in Mbps)

(ii) What is the propagation delay \( L \) of the link? (in ms)

(b) (4 points) Which of the following reflects the Internet’s ‘best effort’ design philosophy? (Select all that apply.)

- [ ] Packets can be dropped
- [ ] Switches have finite buffer capacity
- [ ] Reuse of existing telephone lines
- [ ] Organizing functionality in layers

(c) (4 points) Which of the following design choices helped the Internet to scale? (Select all that apply.)

- [ ] Reuse of existing telephone lines
- [ ] Setting a minimum threshold of acceptable end-to-end packet delay
- [ ] Settling on IP as the common protocol for interconnection
- [ ] Statistical multiplexing at the granularity of individual packets
(d) (4 points) Reverse engineering links characteristics: Consider a link with bandwidth $B$ and latency (i.e. one way propagation delay) $L$, with hosts 1 and 2 attached to opposite ends of the link. Starting at time $t=0$, Host 1 sends two data packets (back-to-back) to Host 2, which ACKs them immediately (requiring no processing time). The ACKs arrive at times $T_1$ and $T_2$. The data packets are of size $P$ and the ACKs are of size $A$. (You may assume $A < P$).

Solve for the link bandwidth $B$ in terms of the arrival times $T_1$ and $T_2$, and the packet sizes $P$ and $A$. The expression for $B$ should not contain $L$ on the right-hand-side.

(e) (2 points) Suppose you would like to urgently deliver 300 TB of data from Boston to Los Angeles. You have available a 1 Gbps dedicated link for data transfer. Which of the following approaches would you prefer to transmit the data?

A. The 1 Gbps link

B. FedEx overnight delivery on a hard drive

(f) (2 points) Indicate which of the following are true:

- Packet switching is more efficient than circuit switching because it uses statistical multiplexing at a finer granularity
- The Internet uses layering to achieve high performance
- The Internet’s use of layering encourages innovation in link technologies
- Transmission time dominates propagation time when transferring a 1GB file over a 1Gbps satellite link that has a propagation delay of 10 seconds
2. **(12 points) Bottleneck Links**

Consider Figure 1 below. Assume that we know the bottleneck link along the path from A to B is the first link with $R_S$ bits/sec. Suppose we send a pair of packets back to back from A to B, and there is no other traffic on this path. Assume each packet of size $L$ bits, and both links have the same propagation delay $d_{prop}$.

![Figure 1: Throughput for a file transfer from server to client](image)

(a) (4 points) Consider Figure 1(a). What is the packet inter-arrival time at the destination? That is, how much time elapses from when the last bit of the first packet arrives until the last bit of the second packet arrives?
(b) (2 points) Again consider Figure 1(a). Now assume that the second link is the bottleneck link (i.e., $R_C < R_S$). Is it possible that the second packet queues at the input queue of the second link? Explain.

(c) (2 points) Once more consider Figure 1(a). Now, suppose that A sends the second packet $T$ seconds after sending the first packet. How large must $T$ be to ensure no queuing before the second link? Explain.

(d) (4 points) Consider Figure 1(b). Suppose that there are $M$ paths between A and B. No two paths share any link. Path $k$ ($k = 1, \ldots, M$) consists of $N$ links with transmission rates $R_{1k}, R_{2k}, \ldots, R_{Nk}$.

(i) If A can only use one path to send data to B, what is the maximum throughput that it can achieve?

(ii) If A can use all $M$ paths to send data, what is the maximum throughput that it can achieve?
3. (10 points) **Circuit Switching**

Consider the circuit-switched network in Figure 2.

(a) (3 points) What is the maximum number of simultaneous connections that can be in progress at any one time in this network? Explain.

(b) (3 points) Suppose that all connections are between switches A and C. What is the maximum number of simultaneous connections that can be in progress? Explain.

(c) (4 points) Suppose we want to make four connections between switches A and C, and another four connections between switches B and D. Can we simultaneously route all eight connections through the network? Explain.

Figure 2: A circuit-switched network consisting of four switches and 16 links.
4. (10 points) **Link Properties**

Suppose two hosts, A and B, are separated by 20,000 kilometers and are connected by a direct link of $R = 2$ Mbps. Suppose the propagation speed over the link is $2.5 \times 10^8$ meters/sec.

(a) (2 points) Calculate the bandwidth-delay product, $R \cdot d_{\text{prop}}$.

(b) (2 points) Consider sending a file of 800,000 bits from Host A to Host B. Suppose the file is sent continuously as one large message. What is the maximum number of bits that will be in the link at any given time?

(c) (3 points) Visualize the link as a pipe filled with a sequence of bits. What is the width (in meters) of a bit in the link, i.e., what fraction of the link corresponds to one bit?

(d) (3 points) Derive a general expression for the width of a bit in terms of the propagation speed $s$, the transmission rate $R$, and the length of the link $m$. 

5. (10 points) **Fun!** The ping program determines the round-trip-time (RTT) to any host in the Internet. Using a computer on campus (either your device connected to AirBears or an instructional machine) ping the following hosts five times each to calculate an ‘average RTT’:

- stanford.edu (Palo Alto, CA)
- cmu.edu (Pittsburgh, PA)
- washington.edu (Seattle, WA)
- cam.ac.uk (Cambridge, UK)
- monash.edu.au (Melbourne, AUS)
- iitd.ac.in (Delhi, India)
- nus.edu.sg (Singapore)
- uwaterloo.ca (Waterloo, Canada)

For each of these cities find the physical distance from Berkeley (You can look these up here: [http://www.geobytes.com/citydistancetool.htm](http://www.geobytes.com/citydistancetool.htm)), and then compute the estimated time $T$ for a packet to reach that location.

(a) (7 points) Plot a graph where the x axis represents the distance to each city, and the y axis represents the ratio between the RTT as measured by the ping program and the shortest possible time $2T$ to reach that city and return. You may disregard transmission delays as ping packets are quite small.

(b) (3 points) What is the ideal ratio? Did you achieve it? Does the ratio increase, decrease, or stay the same as geographical distance increases? Why might this be the case?
