

CS 188: Artificial Intelligence Spring 2006

Lecture 19: Speech Recognition 3/23/2006

Dan Klein – UC Berkeley
Many slides from Dan Jurafsky

Speech in an Hour

- Speech input is an acoustic wave form

Graphs from Simon Arnfield's web tutorial on speech, Sheffield:
<http://www.psy.leeds.ac.uk/research/cogn/speech/tutorial/>

Spectral Analysis

- Frequency gives pitch; amplitude gives volume
 - sampling at ~8 kHz phone, ~16 kHz mic (kHz=1000 cycles/sec)

- Fourier transform of wave displayed as a spectrogram
 - darkness indicates energy at each frequency

Acoustic Feature Sequence

- Time slices are translated into acoustic feature vectors (~39 real numbers per slice)

Digitizing Speech

She just had a baby

- What can we learn from a wavefile?
 - Vowels are voiced, long, loud
 - Length in time = length in space in waveform picture
 - Voicing: regular peaks in amplitude
 - When stops closed: no peaks: silence.
 - Peaks = voicing: .46 to .58 (vowel [iy], from second .65 to .74 (vowel [ax]) and so on
 - Silence of stop closure (1.06 to 1.08 for first [b], or 1.26 to 1.28 for second [b])
 - Fricatives like [sh] intense irregular pattern; see .33 to .46

Examples from Ladefoged

Simple Periodic Sound Waves

- Y axis: Amplitude = amount of air pressure at that point in time
 - Zero is normal air pressure, negative is rarefaction
- X axis: time. Frequency = number of cycles per second.
 - Frequency = 1/Period
 - 20 cycles in .02 seconds = 1000 cycles/second = 1000 Hz

Adding 100 Hz + 1000 Hz Waves

Spectrum

Frequency components (100 and 1000 Hz) on x-axis

Part of [ae] from “had”

- Note complex wave repeating nine times in figure
- Plus smaller waves which repeats 4 times for every large pattern
- Large wave has frequency of 250 Hz (9 times in .036 seconds)
- Small wave roughly 4 times this, or roughly 1000 Hz
- Two little tiny waves on top of peak of 1000 Hz waves

Back to Spectra

- Spectrum represents these freq components
- Computed by Fourier transform, algorithm which separates out each frequency component of wave.

- x-axis shows frequency, y-axis shows magnitude (in decibels, a log measure of amplitude)
- Peaks at 930 Hz, 1860 Hz, and 3020 Hz.

Mel Freq. Cepstral Coefficients

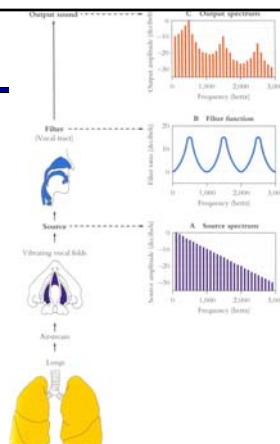

- Do FFT to get spectral information
 - Like the spectrogram/spectrum we saw earlier
- Apply Mel scaling
 - Linear below 1kHz, log above, equal samples above and below 1kHz
 - Models human ear; more sensitivity in lower freqs
- Plus Discrete Cosine Transformation

Final Feature Vector

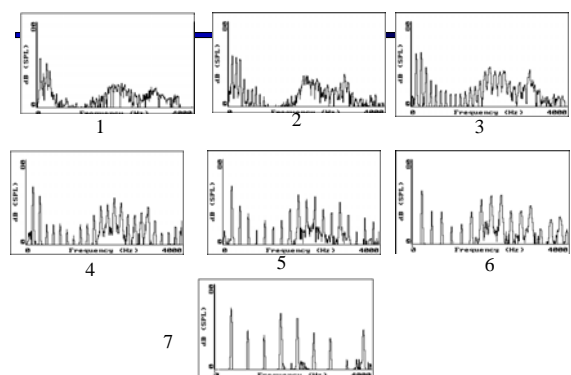

- 39 (real) features per 10 ms frame:
 - 12 MFCC features
 - 12 Delta MFCC features
 - 12 Delta-Delta MFCC features
 - 1 (log) frame energy
 - 1 Delta (log) frame energy
 - 1 Delta-Delta (log frame energy)
- So each frame is represented by a 39D vector
- For your projects:
 - We'll just use two frequencies: the first two formants

Why these Peaks?

- Articulatory facts:
 - Vocal cord vibrations create harmonics
 - The mouth is a selective amplifier
 - Depending on shape of mouth, some harmonics are amplified more than others

Vowel [i] sung at successively higher pitch.

Figures from Ratree Wayland slides from his website

Deriving Schwa

Reminder of basic facts about sound waves

- $f = c/\lambda$
- c = speed of sound (approx 35,000 cm/sec)
- A sound with $\lambda=10$ meters: $f = 35$ Hz (35,000/1000)
- A sound with $\lambda=2$ centimeters: $f = 17,500$ Hz (35,000/2)

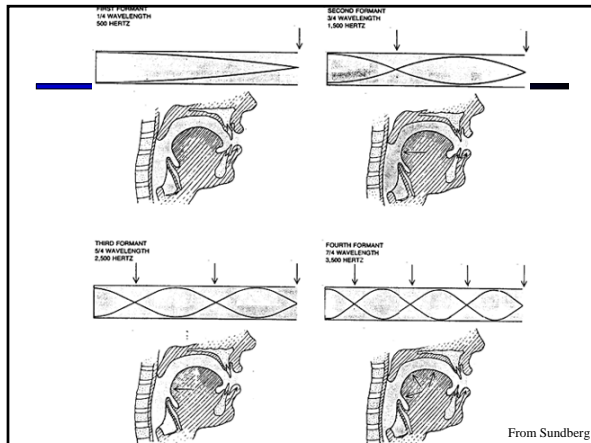

Resonances of the vocal tract

The human vocal tract as an open tube

- Air in a tube of a given length will tend to vibrate at resonance frequency of tube.
- Constraint: Pressure differential should be maximal at (closed) glottal end and minimal at (open) lip end.

Figure from W. Barry Speech Science slides

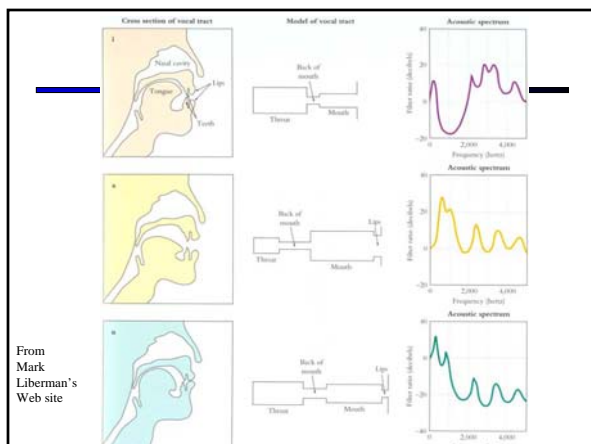

Computing the 3 Formants of Schwa

Let the length of the tube be L

- $F_1 = c/\lambda_1 = c/(4L) = 35,000/4 \cdot 17.5 = 500\text{Hz}$
- $F_2 = c/\lambda_2 = c/(4/3L) = 3c/4L = 3 \cdot 35,000/4 \cdot 17.5 = 1500\text{Hz}$
- $F_3 = c/\lambda_3 = c/(4/5L) = 5c/4L = 5 \cdot 35,000/4 \cdot 17.5 = 2500\text{Hz}$

- So we expect a neutral vowel to have 3 resonances at 500, 1500, and 2500 Hz

- These vowel resonances are called **formants**

From Mark Liberman's Web site

Seeing formants: the spectrogram

How to read spectrograms

- bab: closure of lips lowers all formants: so rapid increase in all formants at beginning of "bab"
- dad: first formant increases, but F2 and F3 slight fall
- gag: F2 and F3 come together: this is a characteristic of velars. Formant transitions take longer in velars than in alveolars or labials

From Ladefoged "A Course in Phonetics"

HMMs for Speech

HMMs for Continuous Observations?

- Before: discrete, finite set of observations
- Now: spectral feature vectors are real valued!
- Solution 1: discretization
- Solution 2: continuous emissions models
 - Gaussians
 - Multivariate Gaussians
 - Mixtures of Multivariate Gaussians
- A state is progressively:
 - Context independent subphone (~3 per phone)
 - Context dependent phone (=triphones)
 - State-tying of CD phone

Viterbi Decoding

ASR Lexicon: Markov Models

Viterbi with 2 Words + Unif. LM

- Null transition from the end state of each word to start state of all (both) words.

Figure from Huang et al page 612

Markov Process with Unigram LM

Figure from Huang et al page 617

Markov Process with Bigrams
