## CS 188: Artificial Intelligence

## Bayes' Nets

Instructors: Sergey Levine --- University of California, Berkeley

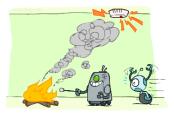

#### Reminders

- A probability model specifies a probability for every possible world
  - Typically, possible worlds are defined by assignments to a set of variables  $X_1, \dots, X_n$
  - In that case, the probability model is a joint distribution  $P(X_1, ..., X_n)$
  - Written as a table, this would be exponential in n
- Independence: joint distribution = product of marginal distributions
  - $P(x,y) = P(x)P(y) \text{ or } P(x) = P(x \mid y)$
  - E.g., probability model for n coins represented by n numbers instead of  $2^n$
- Independence is rare in practice: within a domain, most variables correlated
- Conditional independence is much more common:
  - Toothache and Catch are conditionally independent given Cavity
  - Traffic and Umbrella are conditionally independent given Rain
  - Alarm and Fire are conditionally independent given Smoke
  - Reading1 and Reading2 are conditionally independent given Ghost location

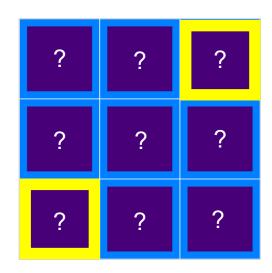

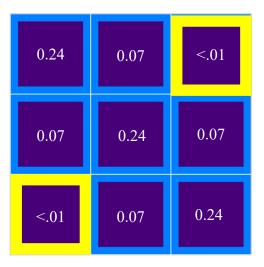

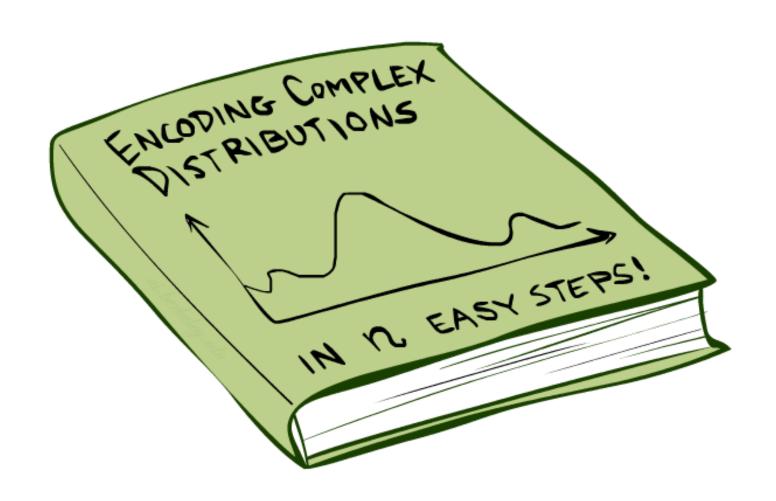

### Ghostbusters, Revisited

- What about two readings? What is  $P(r_1,r_2 \mid g)$ ?
- Readings are conditionally independent given the ghost location!
- $P(r_1,r_2 | g) = P(r_1 | g) P(r_2 | g)$
- Applying Bayes' rule in full:
- $P(g | r_1, r_2) \propto P(r_1, r_2 | g) P(g)$ =  $P(g) P(r_1 | g) P(r_2 | g)$
- Bayesian updating using low-dimensional conditional distributions!!

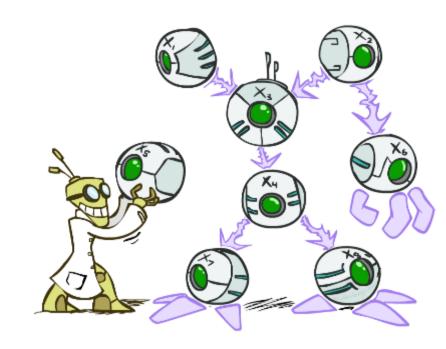

## Bayes Nets: Big Picture

#### Bayes Nets: Big Picture

- Bayes nets: a technique for describing complex joint distributions (models) using simple, local distributions (conditional probabilities)
  - A subset of the general class of graphical models
- Take advantage of local causality:
  - the world is composed of many variables,
  - each interacting locally with a few others
- For about 10 min, we'll be vague about how these interactions are specified

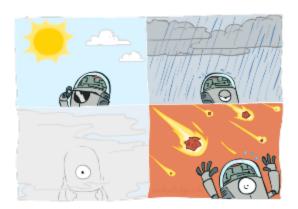

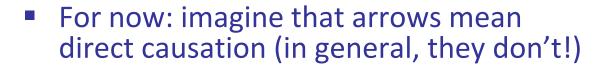

## **Graphical Model Notation**

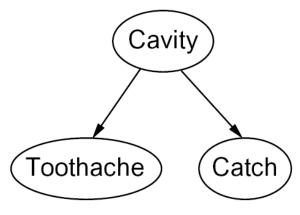

- Nodes: variables (with domains)
  - Can be assigned (observed) or unassigned (unobserved)

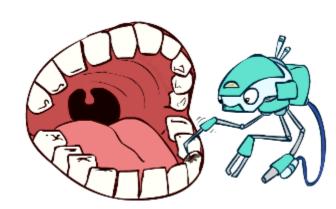

- Arcs: interactions
  - Similar to CSP constraints
  - Indicate "direct influence" between variables
  - Formally: encode conditional independence (more later)

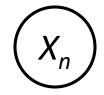

### Example: Coin Flips

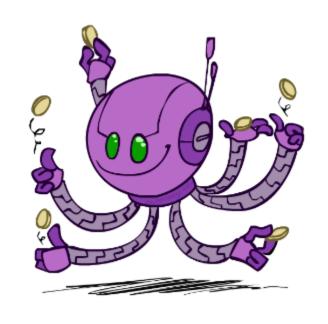

N independent coin flips

No interactions between variables: absolute independence

# Example: Traffic

#### Variables:

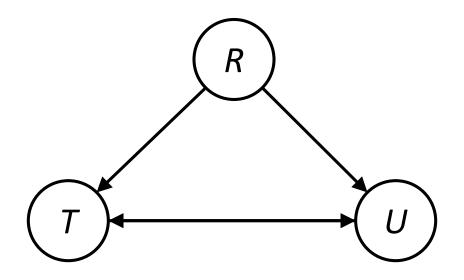

■ T: There is traffic

U: I'm holding my umbrella

R: It rains

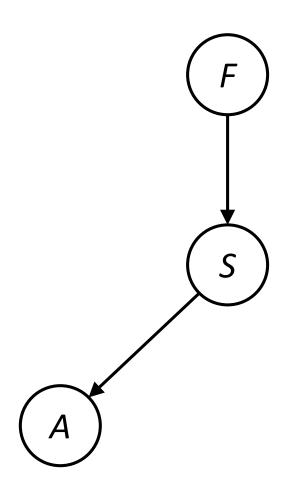

## Example: Smoke alarm

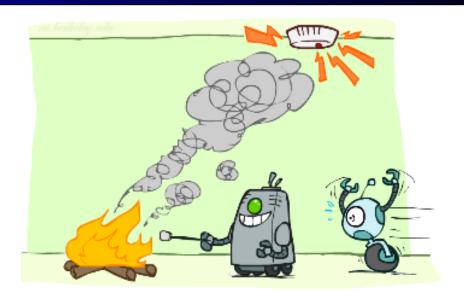

#### Variables:

• F: There is fire

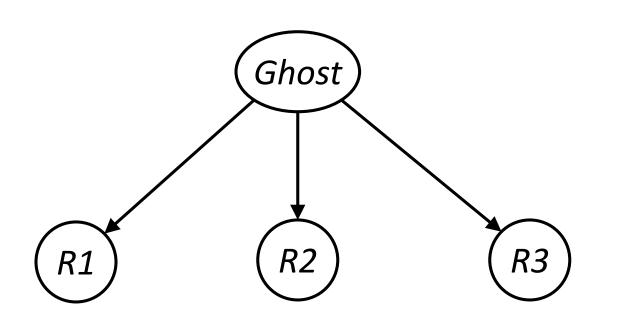

S: There is smoke

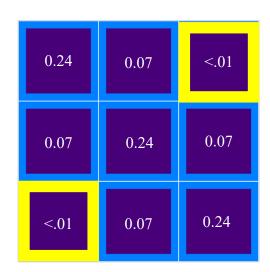

A: Alarm sounds

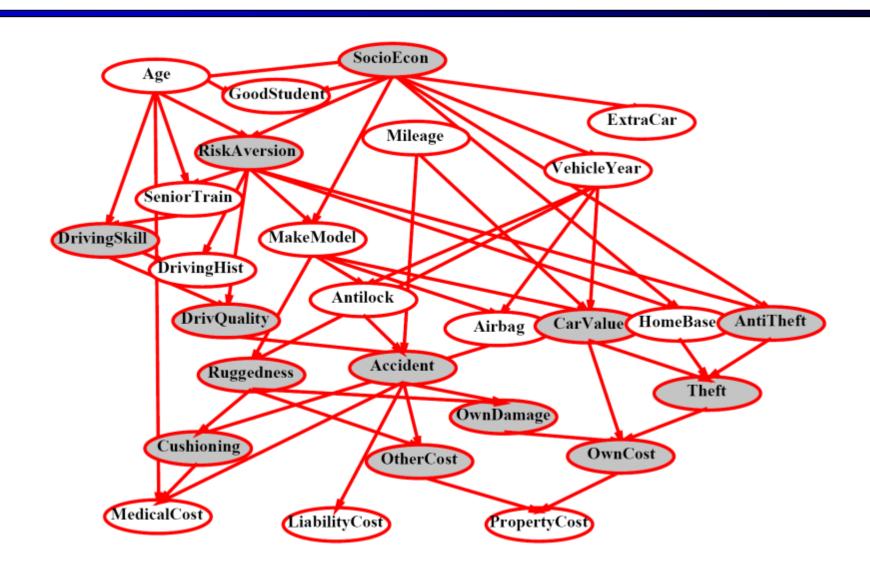

## **Example: Ghostbusters**

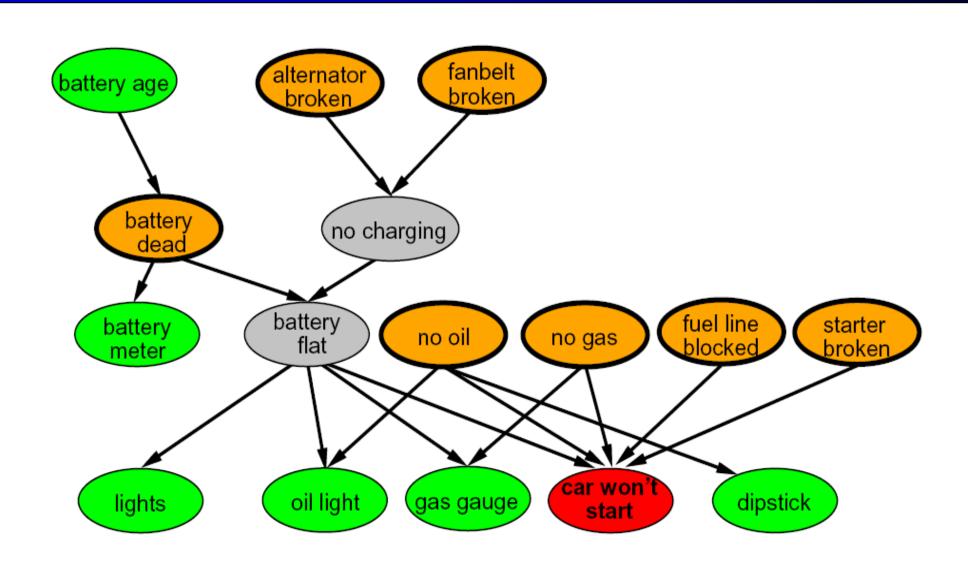

## Example Bayes' Net: Insurance

# Example Bayes' Net: Car

#### Can we build it?

#### Variables

T: Traffic

R: It rains

L: Low pressure

■ D: Roof drips

■ B: Ballgame

• C: Cavity

## Can we build it?

#### Variables

■ B: Burglary

A: Alarm goes off

M: Mary calls

■ J: John calls

■ E: Earthquake!

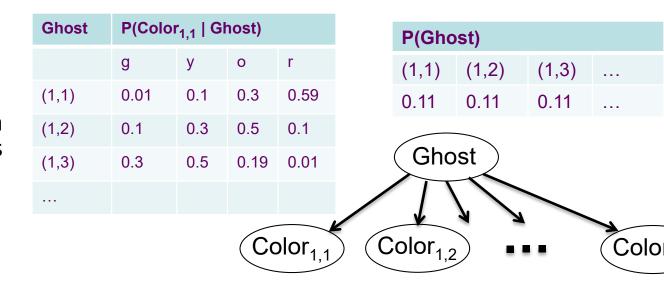

# Bayes Net Syntax and Semantics

#### **Bayes Net Syntax**

- A set of nodes, one per variable X<sub>i</sub>
- A directed, acyclic graph
- A conditional distribution for each node given its parent variables in the graph
  - CPT: conditional probability table: each row is a distribution for child given a configuration of its parents
  - Description of a noisy "causal" process

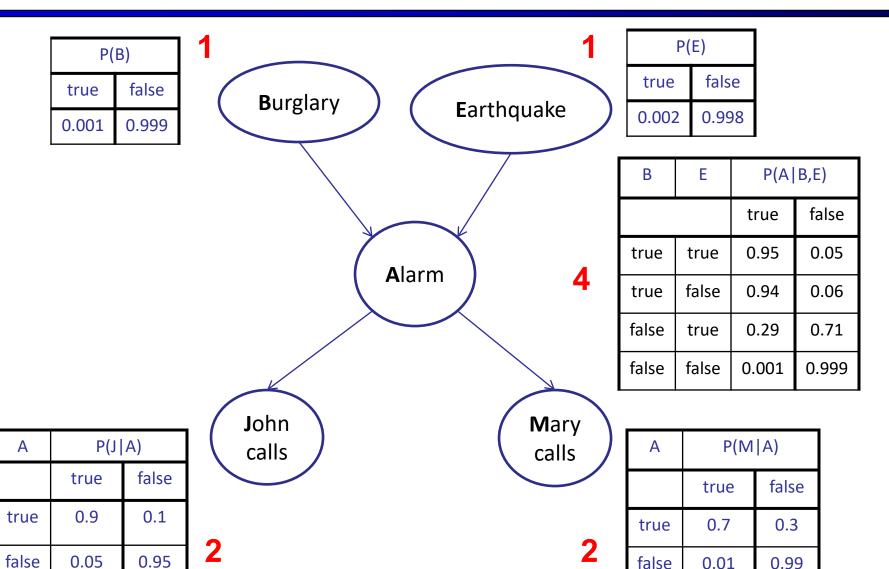

A Bayes net = Topology (graph) + Local Conditional Probabilities

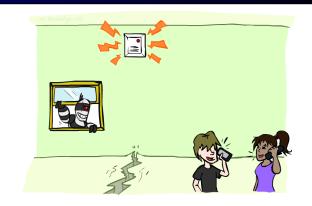

#### Example: Alarm Network

false

0.01

0.99

Number of free parameters in each CPT:

Parent domain sizes d<sub>1</sub>,...,d<sub>k</sub>

Child domain size d Each table row must sum to 1

 $(d-1) \Pi_i d_i$ 

### General formula for sparse BNs

- Suppose
  - n variables
  - Maximum domain size is d
  - Maximum number of parents is k
- Full joint distribution has size  $O(d^n)$
- Bayes net has size  $O(n \cdot d^k)$ 
  - Linear scaling with n as long as causal structure is local

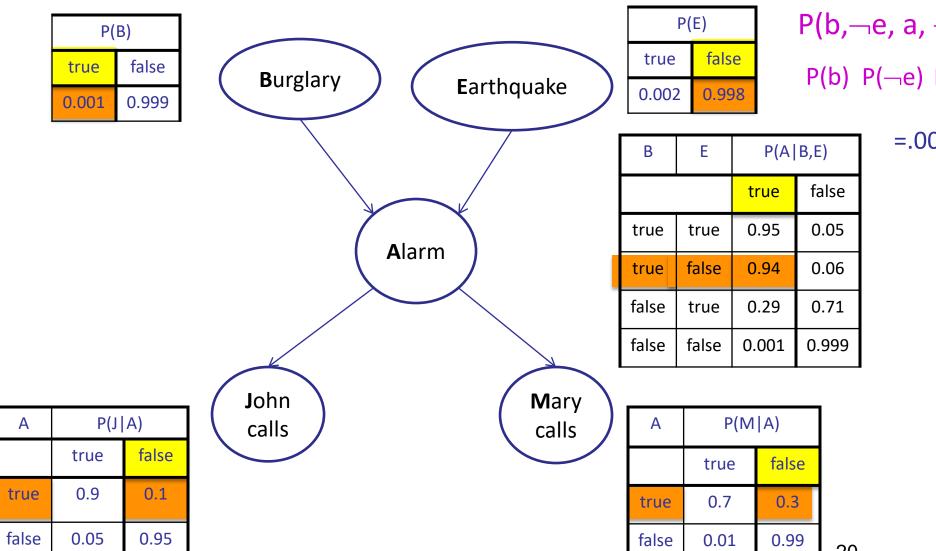

## Bayes net global semantics

Bayes nets encode joint distributions as product of conditional distributions on each variable:

$$P(X_1,...,X_n) = \prod_i P(X_i \mid Parents(X_i))$$

### Example

 $P(b,\neg e, a, \neg j, \neg m) =$   $P(b) P(\neg e) P(a|b,\neg e) P(\neg j|a) P(\neg m|a)$

#### Probabilities in BNs

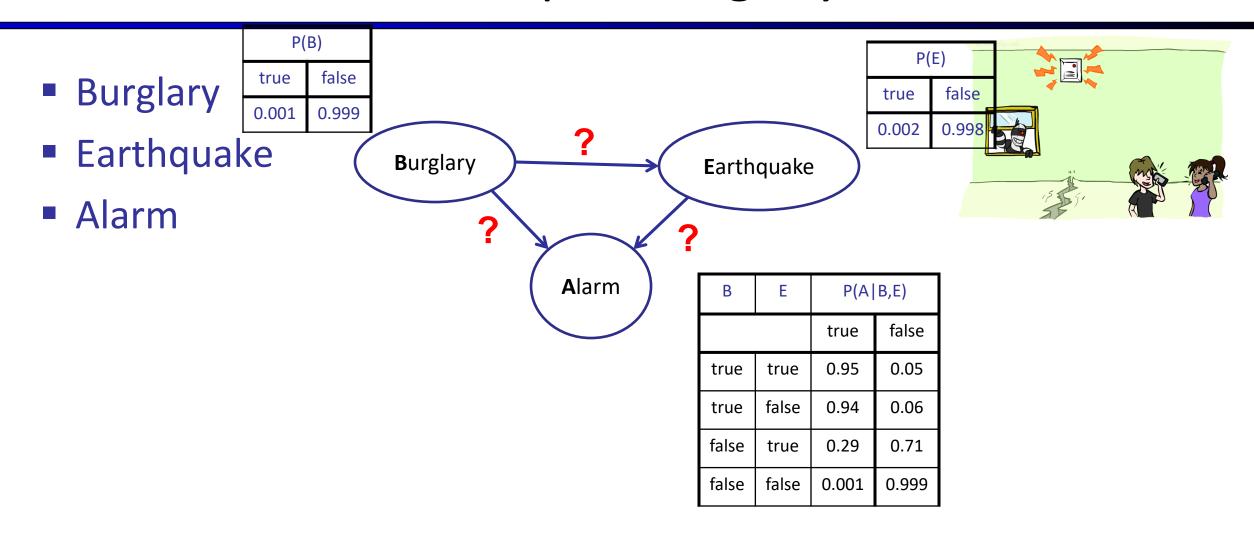

Why are we guaranteed that setting

$$P(X_1,...,X_n) = \prod_i P(X_i \mid Parents(X_i))$$

results in a proper joint distribution?

- Chain rule (valid for all distributions):  $P(X_1,...,X_n) = \prod_i P(X_i \mid X_1,...,X_{i-1})$
- Assume conditional independences:  $P(X_i \mid X_1,...,X_{i-1}) = P(X_i \mid Parents(X_i))$ 
  - When adding node  $X_i$ , ensure parents "shield" it from other predecessors
- $\rightarrow$  Consequence:  $P(X_1,...,X_n) = \prod_i P(X_i \mid Parents(X_i))$
- So the topology implies that certain conditional independencies hold

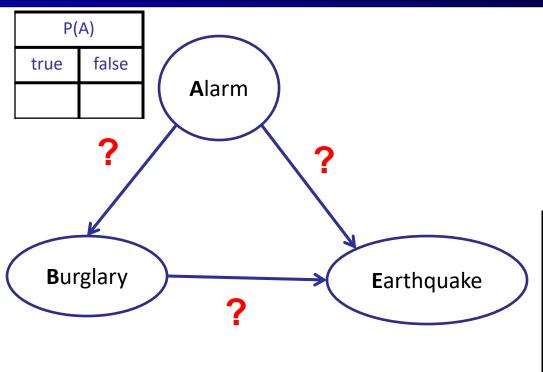

## **Example: Burglary**

## **Example: Burglary**

- Alarm
- Burglary
- Earthquake

Α	P(B A)		
	true	false	
true	?		
false			

Α	В	P(E A,B)	
		true	false
true	true		
true	false		
false	true		
false	false		

## Causality?

#### When Bayes nets reflect the true causal patterns:

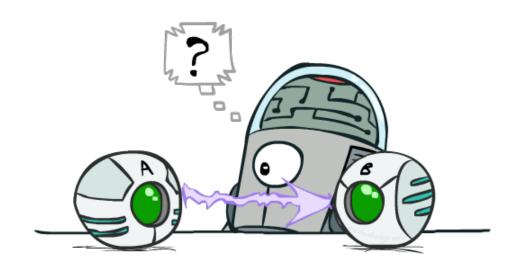

- Often simpler (fewer parents, fewer parameters)
- Often easier to assess probabilities
- Often more robust: e.g., changes in frequency of burglaries should not affect the rest of the model!

#### BNs need not actually be causal

- Sometimes no causal net exists over the domain (especially if variables are missing)
- E.g. consider the variables *Traffic* and *Umbrella*
- End up with arrows that reflect correlation, not causation

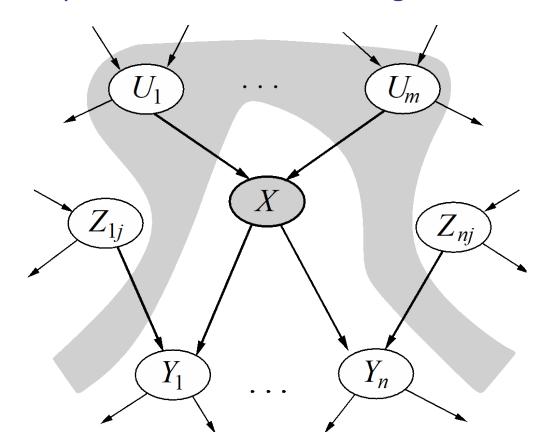

#### What do the arrows really mean?

- Topology may happen to encode causal structure
- Topology really encodes conditional independence:  $P(X_i \mid X_1,...,X_{i-1}) = P(X_i \mid Parents(X_i))$

## Conditional independence semantics

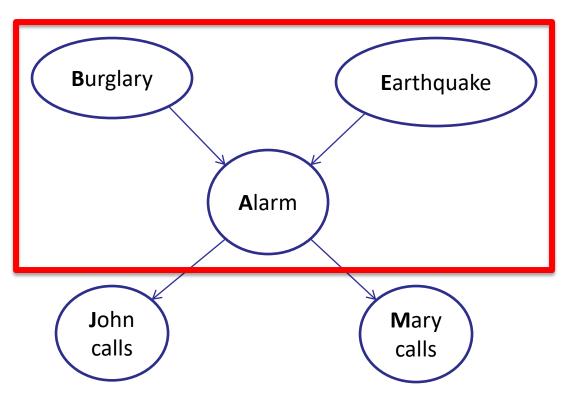

- Every variable is conditionally independent of its non-descendants given its parents
- Conditional independence semantics <=> global semantics

## Example

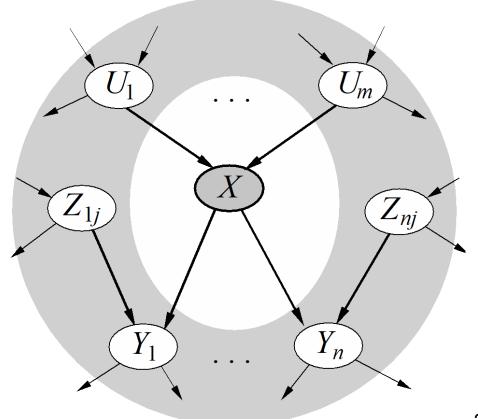

- JohnCalls independent of Burglary given Alarm?
  - Yes
- JohnCalls independent of MaryCalls given Alarm?
  - Yes
- Burglary independent of Earthquake?
  - Yes
- Burglary independent of Earthquake given Alarm?
  - NO!
  - Given that the alarm has sounded, both burglary and earthquake become more likely
  - But if we then learn that a burglary has happened, the alarm is explained away and the probability of earthquake drops back

#### V-structure

#### Markov blanket

- A variable's Markov blanket consists of parents, children, children's other parents
- Every variable is conditionally independent of all other variables given its Markov blanket

## **Bayes Nets**

- So far: how a Bayes net encodes a joint distribution
- Next: how to answer queries, i.e., compute conditional probabilities of queries given evidence
