Object-Centric Averages by Torralba (2001)

Manual Annotation and Alignment

Average Image

Slide by Jun-Yan Zhu
Computing Means

Two Requirements:
• Alignment of objects
• Objects must span a subspace

Useful concepts:
• Subpopulation means
• Deviations from the mean
Images as Vectors

\[ n \times m = n \times m \]
Vector Mean: Importance of Alignment

\[ \frac{1}{2} + \frac{1}{2} = \text{mean image} \]
How to align faces?

http://www2.imm.dtu.dk/~aam/datasets/datasets.html
Shape Vector

Provides alignment!
Average Face

1. Warp to mean shape
2. Average pixels

Appearance Vectors vs. Shape Vectors

**Appearance Vector**
- 200*150 pixels (RGB)
- Requires Annotation
- Provides alignment!

**Shape Vector**
- 43 coordinates (x,y)
- Vector of 43*2 Dimensions

Slide by Kevin Karsch
Objects must span a subspace
Example

Does not span a subspace
Subpopulation means

Examples:
- Male vs. female
- Happy vs. said
- Average Kids
- Happy Males
- Etc.
- [http://www.faceresearch.org](http://www.faceresearch.org)

Average kid
Average happy male
Average female
Average male
Average Women of the world
Average Men of the world
Deviations from the mean

\[ \Delta X = X - \bar{X} \]
Deviations from the mean

\[ \Delta X = X - \bar{X} \]

\[ X = 3 + 1.7 \]
Extrapolating faces

- We can imagine various meaningful directions.
Manipulating faces

- How can we make a face look more female/male, young/old, happy/sad, etc.?
- [http://www.faceresearch.org/demos/transform](http://www.faceresearch.org/demos/transform)
Manipulating Facial Appearance through Shape and Color

Duncan A. Rowland and David I. Perrett

*St Andrews University*

IEEE CG&A, September 1995
Face Modeling

Compute *average* faces (color and shape)

Compute *deviations* between male and female (vector and color differences)
Changing gender

Deform shape and/or color of an input face in the direction of “more female”

original

(a) shape

(b) both

(c) color

(d) both
Enhancing gender

more same original androgynous more opposite
Changing age

Face becomes “rounder” and “more textured” and “grayer”

original shape

original color

shape both

color both
Back to the Subspace
Linear Subspace: convex combinations

Any new image $X$ can be obtained as weighted sum of stored “basis” images.

$$X = \sum_{i=1}^{m} a_i X_i$$

Our old friend, change of basis! What are the new coordinates of $X$?
The Morphable Face Model

The actual structure of a face is captured in the shape vector $\mathbf{S} = (x_1, y_1, x_2, \ldots, y_n)^T$, containing the $(x, y)$ coordinates of the $n$ vertices of a face, and the appearance (texture) vector $\mathbf{T} = (R_1, G_1, B_1, R_2, \ldots, G_n, B_n)^T$, containing the color values of the mean-warped face image.
The Morphable face model

Again, assuming that we have \( m \) such vector pairs in full correspondence, we can form new shapes \( S_{\text{model}} \) and new appearances \( T_{\text{model}} \) as:

\[
S_{\text{model}} = \sum_{i=1}^{m} a_i S_i \quad \text{and} \quad T_{\text{model}} = \sum_{i=1}^{m} b_i T_i
\]

If number of basis faces \( m \) is large enough to span the face subspace then:

Any new face can be represented as a pair of vectors \((\alpha_1, \alpha_2, \ldots, \alpha_m)^T\) and \((\beta_1, \beta_2, \ldots, \beta_m)^T\)!
Issues:

1. How many basis images is enough?
2. Which ones should they be?
3. What if some variations are more important than others?
   - E.g. corners of mouth carry much more information than haircut

Need a way to obtain basis images automatically, in order of importance!

But what’s important?
Principal Component Analysis

Given a point set \( \{\vec{p}_j\}_{j=1}^P \), in an \( M \)-dim space, PCA finds a basis such that

- coefficients of the point set in that basis are uncorrelated
- first \( r < M \) basis vectors provide an approximate basis that minimizes the mean-squared-error (MSE) in the approximation (over all bases with dimension \( r \))
PCA via Singular Value Decomposition

\[ [u, s, v] = \text{svd}(A); \]

Choosing subspace dimension $r^*$:

- look at decay of the eigenvalues as a function of $r$
- Larger $r$ means lower expected error in the subspace data approximation
EigenFaces

First popular use of PCA on images was for modeling and recognition of faces [Kirby and Sirovich, 1990, Turk and Pentland, 1991]

- Collect a face ensemble
- Normalize for contrast, scale, & orientation.
- Remove backgrounds
- Apply PCA & choose the first $N$ eigen-images that account for most of the variance of the data.

http://vimeo.com/23561002
Challenges

Non-rigid (facial expressions, age...)
Occlusions (hair, glasses ...)
Arbitrary lighting, pose
Different cameras, exposure, focus ...

But: there are many photos!
