61A Lecture 35

Monday, November 26
Distributed Computing

A distributed computing application consists of multiple programs running on multiple computers that together coordinate to perform some task.

- Computation is performed in parallel by many computers.
- Information can be restricted to certain computers.
- Redundancy and geographic diversity improve reliability.

Characteristics of distributed computing:
- Computers are independent — they do not share memory.
- Coordination is enabled by messages passed across a network.
- Individual programs have differentiating roles.

Distributed computing for large-scale data processing:
- Databases respond to queries over a network.
- Data sets can be spread across multiple machines (Wednesday).
Network Messages

Computers communicate via messages: sequences of bytes transmitted over a network.

Messages can serve many purposes:
- **Send data** to another computer
- **Request data** from another computer
- **Instruct** a program to **call a function** on some arguments.
- **Transfer a program** to be executed by another computer.

Messages conform to a **message protocol** adopted by both the sender to encode the message & the receiver to interpret it.
- For example, bits at fixed positions may have fixed meanings.
- Components of a message may be separated by delimiters.
- Protocols are designed to be implemented by many different programming languages on a variety of platforms.
The Internet Protocol

The Internet Protocol (IP) specifies how to transfer packets of data among different networks.

- Networks are inherently unreliable at any point.
- The structure of a network is dynamic.
- No system exists to monitor or track communications.

Packets are forwarded toward their destination using simple rules on a best-effort basis.

http://en.wikipedia.org/wiki/IPv4
Transmission Control Protocol

The design of the **Internet Protocol** (IP) imposes constraints:
- Packets are limited to 65,535 bytes each.
- Packets may arrive in a different order than they were sent.
- Packets may be duplicated or lost.

The **Transmission Control Protocol** (TCP) improves reliability:
- Ordered, reliable transmission of arbitrary byte streams.
- Implemented using the IP.
- Correctly orders packets by including sequence numbers.
- Removes duplicates; requests retransmission of lost packets.

TCP connection initiates with a "handshake" procedure.
- What's the minimum number of messages needed to prove to both computers that two-way communication is possible?

5
Message Sequence of a TCP Connection

Computer A

Establishes packet numbering system

Synchronization request

Acknowledgement & synchronization request

Acknowledgement

Data message from A to B

Data message from B to A

Termination signal

Acknowledgement & termination signal

Acknowledgement

Computer B
Client/Server Architecture

One server provides information to multiple clients through request and response messages.

**Server role:** Respond to service requests with requested information.

**Client role:** Request information and make use of the response.

**Abstraction:** The client knows what service a server provides but not how it is provided.
Client/Server Example: The World Wide Web

The **client** is a web browser (e.g., Firefox):
- Request content from a location on behalf of the user.
- Display the content to the user.

The **server** is a web server (e.g., www.nytimes.com)
- Respond with (perhaps personalized) content at that location.

---

**Diagram:**
- Web browser
- Web server
- TCP Initialization Handshake
- HTTP GET request of content
- HTTP response with content
- Follow-up requests for auxiliary content

---

8
The Hypertext Transfer Protocol

The Hypertext Transfer Protocol (HTTP) is a protocol designed to implement a Client/Server architecture.

Browser issues a GET request to www.nytimes.com for the content (resource) at location "pages/todayspaper".

Server response contains more than just the resource itself:
- Status code, e.g. 200 OK, 404 Not Found, 403 Forbidden, etc.
- Date of response; type of server responding
- Last-modified time of the resource
- Type of content and length of content

Demo
Properties of a Client/Server Architecture

**Benefits:**
- Creates a separation of concerns among components.
- Enforces an abstraction barrier between client and server.
- A centralized server can reuse computation across clients.

**Liabilities:**
- A single point of failure: the server.
- Computing resources become scarce with increasing demand.

**Common use cases:**
- Databases — The database serves responses to query requests.
- Open Graphics Library (OpenGL) — A graphics processing unit (GPU) serves images to a central processing unit (CPU).
- File and resource transfer: HTTP, FTP, email, etc.
Peer-to-Peer Architecture

All participants in a distributed application contribute computational resources: processing, storage, and network. Messages are relayed through a network of participants. Each participant has only partial knowledge of the network.
Network Structure Concerns

Some data transfers on the Internet are faster than others.

The time required to transfer a message through a peer-to-peer network depends on the route chosen.
Example: Skype

Skype is a Voice Over IP (VOIP) system that uses a hybrid peer-to-peer architecture.

Login & contacts are handled via a centralized server.

Conversations between two computers that cannot send messages to each other directly are relayed through *supernodes*.

Any Skype client with its own IP address may be a supernode.
