Pairs Review
Pairs and Lists

In the late 1950s, computer scientists used confusing names
- **cons**: Two-argument procedure that creates a pair
- **car**: Procedure that returns the first element of a pair
- **cdr**: Procedure that returns the second element of a pair
- **nil**: The empty list

A (non-empty) list in Scheme is a pair in which the second element is **nil** or a Scheme list

**Important!** Scheme lists are written in parentheses separated by spaces

A dotted list has some value for the second element of the last pair that is not a list

> (define x (cons 1 2))
> x
(1 . 2)
> (car x)
1
> (cdr x)
2
> (cons 1 (cons 2 (cons 3 (cons 4 nil))))
(1 2 3 4)

(Demo)
Scheme Lists and Quotation

Dots can be used in a quoted list to specify the second element of the final pair.

```scheme
> (cdr (cdr '(1 2 . 3)))
3
```

However, dots appear in the output only of ill-formed lists.

```scheme
> '(1 2 . 3)
(1 2 . 3)
> '(1 2 . (3 4))
(1 2 3 4)
> '(1 2 3 . nil)
(1 2 3)
```

What is the printed result of evaluating this expression?

```scheme
> (cdr '((1 2 . (3 4 . (5)))))
(3 4 5)
```
Exceptions
Today's Topic: Handling Errors

Sometimes, computer programs behave in non-standard ways
• A function receives an argument value of an improper type
• Some resource (such as a file) is not available
• A network connection is lost in the middle of data transmission

Grace Hopper's Notebook, 1947, Moth found in a Mark II Computer
Exceptions

A built-in mechanism in a programming language to declare and respond to exceptional conditions

Python raises an exception whenever an error occurs.

Exceptions can be handled by the program, preventing the interpreter from halting.

Unhandled exceptions will cause Python to halt execution and print a stack trace.

Mastering exceptions:

Exceptions are objects! They have classes with constructors.

They enable non-local continuations of control

If f calls g and g calls h, exceptions can shift control from h to f without waiting for g to return.

(Exception handling tends to be slow.)
Raising Exceptions
Assert Statements

Assert statements raise an exception of type AssertionError

```
assert <expression>, <string>
```

Assertions are designed to be used liberally. They can be ignored to increase efficiency by running Python with the "-O" flag; "O" stands for optimized

```
python3 -O
```

Whether assertions are enabled is governed by a bool `__debug__`

(Demo)
Raise Statements

Exceptions are raised with a raise statement

```
raise <expression>
```

<expression> must evaluate to a subclass of BaseException or an instance of one

Exceptions are constructed like any other object. E.g., `TypeError('Bad argument!')`

- **TypeError** -- A function was passed the wrong number/type of argument
- **NameError** -- A name wasn't found
- **KeyError** -- A key wasn't found in a dictionary
- **RuntimeError** -- Catch-all for troubles during interpretation

(Demo)
Try Statements
Try Statements

Try statements handle exceptions

```
try:
    <try suite>
except <exception class> as <name>:
    <except suite>
...
```

Execution rule:

The <try suite> is executed first

If, during the course of executing the <try suite>, an exception is raised that is not handled otherwise, and

If the class of the exception inherits from <exception class>, then

The <except suite> is executed, with <name> bound to the exception
Handling Exceptions

Exception handling can prevent a program from terminating

```python
>>> try:
    x = 1/0
    except ZeroDivisionError as e:
        print('handling a', type(e))
    x = 0

handling a <class 'ZeroDivisionError'>
```

```
>>> x
0
```

**Multiple try statements**: Control jumps to the except suite of the most recent try statement that handles that type of exception

(Demo)
How will the Python interpreter respond?

```python
def invert(x):
    inverse = 1/x  # Raises a ZeroDivisionError if x is 0
    print('Never printed if x is 0')
    return inverse

def invert_safe(x):
    try:
        return invert(x)
    except ZeroDivisionError as e:
        return str(e)

>>> invert_safe(1/0)
>>> try:
...     invert_safe(0)
... except ZeroDivisionError as e:
...     print('Handled!')
>>> inverrrrt_safe(1/0)
```

WWPD: What Would Python Do?
Example: Reduce
Reducing a Sequence to a Value

```python
def reduce(f, s, initial):
    """Combine elements of \( s \) pairwise using \( f \), starting with \( \text{initial} \).

E.g., \( \text{reduce}(\text{mul}, [2, 4, 8], 1) \) is equivalent to \( \text{mul}(\text{mul}(1, 2), 4), 8) \).

>>> \text{reduce}(\text{mul}, [2, 4, 8], 1)
64
"""
```

\( f \) is...
\( s \) is...
\( \text{initial} \) is...

\( f \) is ... 
a two-argument function

\( s \) is ...
a sequence of values that can be the second argument

\( \text{initial} \) is ... 
a value that can be the first argument
