COMPUTER SCIENCE IN THE NEWS

Sing for the win

A new app game developed by a Cambridge student challenges people to sing the right note at the right time in order to smash down a wall and advance to the next level - surreptitiously engaging them with basic music theory at the same time.

- Review: Streams
- Logic programming
- PyGic
REVIEW: STREAMS

What are the first five elements of the stream

\[
s = \text{Stream}(1, \\
\quad \text{lambda:} \\
\quad \quad \text{Stream}(3, \\
\quad \quad \text{lambda:} \\
\quad \quad \quad \text{mul_streams}(s, \\
\quad \quad \quad \quad s.\text{rest})))
\]
**Review: Streams**

The stream we have to determine:

<table>
<thead>
<tr>
<th>s</th>
<th>1</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>s.rest</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

The streams it depends on:
When you add to the main stream, update all the other streams that depend on it!
**Review: Streams**

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>3</th>
<th>3</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>s</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>s.rest</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
REVIEW: STREAMS

\[
\begin{array}{cccccc}
  s & 1 & 3 & 3 & 9 & 27 & \ldots \\
  s & 1 & 3 & 3 & 9 \\
  s\text{.rest} & 3 & 3 & 9 \\
\end{array}
\]
In most of our programs so far, we have described *how to* compute a certain value or to perform a certain task.

```python
def abs(x):
    if x >= 0:
        return x
    return -x
```

- To find the absolute value of \( x \)...
- ... Check if \( x \) is greater than, or equal to, zero.
- If so, return the number itself.
- Otherwise, return the negative of the number.
We found an algorithm to solve a problem, and we wrote the corresponding program that told the computer to follow a series of steps.

This is known as imperative programming.
THE PROBLEM WITH IMPERATIVE PROGRAMMING

Sometimes, we do not know exactly how to solve a problem, but we do know what the solution is.

For example, what is the square root of a number $y$?

It is a number $x$ such that $x^2 = y$. 
THE PROBLEM WITH IMPERATIVE PROGRAMMING

The definition of a square root does not tell us *how* to find it, but it does tell us *what* it is.

Of course, we have many methods to find square roots: we can use Newton’s method, or we can square all numbers smaller than $y$.

But, we would still be telling the computer *how* to solve the problem!
THE PROBLEM WITH IMPERATIVE PROGRAMMING

Problem:
Can we express our problems in a way similar to how they were defined?
Can we provide a set of definitions and descriptions of what we want, and leave it to the computer to deduce how to solve it?
ANNOUNCEMENTS

• Homework 13 due **Saturday, August 4**.
  – Includes Py, streams, iterators, and generators
  – Also includes the Project 4 contest.

• Project 4 due **Tuesday, August 7**.
  – Partnered project, in two parts.
  – Twelve questions, so *please start early*!
  – Two extra credit questions.

• De-stress potluck on **Thursday, August 2 from 7pm to 10pm** in the **Wozniak Lounge** (Soda, 4th floor).
  – Food and games.
  – Come and leave when you want.
ANNOUNCEMENTS: FINAL

• Final is **Thursday, August 9.**
  – *Where?* 1 Pimentel.
  – *When?* 6PM to 9PM.
  – *How much?* All of the material in the course, from June 18 to August 8, will be tested.

• Closed book and closed electronic devices.
• One 8.5” x 11” ‘cheat sheet’ allowed.
• No group portion.
• We will get back to you today if you have conflicts and have told us. If you haven’t told us yet, please *let us know.*
DECLARATIVE PROGRAMMING

In *declarative programming*, we describe *what* the properties of the required solution are, and the computer discovers how to find the solution.

For example, we give a computer the definition of the square root of a number, and it discovers how to find the square root of the number.
In general, declarative programming is very hard and is an active field of research.

*Logic programming* is a type of declarative programming that uses mathematical logic and logical inference to solve a problem.
LOGIC PROGRAMMING

One of the most commonly used logic programming languages is Prolog.

Prolog was designed in 1972 by Alain Colmerauer for use in natural language processing. We will use and study a very simplified Python-based version of Prolog.
PyGic

PyGic is a logic programming language, with design inspired by Prolog, but with a Python-like syntax.

Jon coded it and is pretty proud of it. 😊 Stephen Martinis and Eric Kim also helped.

We will use it to explore some of the principles behind logic programming.
**PyGIC: Facts**

We will start by stating the facts that we know.

P?> fact likes(jon, ice_cream)  
Yes.
P?> fact likes(tom, ice_cream)  
Yes.
P?> fact likes(jon, coffee)  
Yes.
P?> fact father(james, harry)  
Yes.
P?> fact mother(lily, harry)  
Yes.
P?> fact father(harry, albus_severus)  
Yes.
P?> fact father(harry, james_sirius)  
Yes.

The interpreter will only respond with Yes. or No.
The Yes. here indicates that the interpreter has accepted our fact.
PyGic: Facts

A fact allows us to tell the computer what we know to be true, and what it can build up from.

It looks like a function, but it is not.

A fact establishes a relation between different objects. It does not compute a value, whereas a function would.
PyGic: Queries and Variables

We can now perform simple queries.

\[ \text{P?} \rightarrow \text{likes(jon, ?what)} \]

Yes.

\[ \text{?what} = \text{ice_cream} \]

Variables are denoted with a question mark at the front.

Variables indicate things we do not know. Here, for example, we do not know what Jon likes.
We can now perform simple queries.

P?> likes(jon, ?what)

Yes.  The interpreter is able to find a match among the facts we gave it!

?what = ice_cream  It finds that if ?what were replaced by ice_cream, it gets a fact.
PYGIC: QUERIES AND VARIABLES

P?> more?
Yes.
?what = coffee
P?> more?
No.

Are there any more things that Jon likes?
The interpreter finds another match!
Are there any more things that Jon likes?
The interpreter cannot find any more matches.
PyGic: Queries and Variables

We assert facts and the interpreter stores them in a database.

When we perform simple queries, we use variables to denote values that we do not know. The interpreter then matches the query against the facts that it knows. If it finds a match, it shows the values for the variables in that match.
PYGIC: QUERIES AND VARIABLES

The interpreter can only match against the facts that it knows. It \textit{cannot} match against facts that have not been established.

Jon could like other things, but the interpreter does not know about these things.

This is the \textit{closed world assumption}: the interpreter only knows what is given to it.
**PyGic: Queries and Variables**

The interpreter finds all possible matches to your query, and you can have as many variables as you will need in your query.

For example, what would the interpreter respond to the following query?

```
P>? likes(who, what)
```
The interpreter matches the pattern of the query to the patterns of the facts in its database.

This process of pattern matching is called unification.
We can also represent *lists* in PyGic.

\[ \text{P?> less\_than\_4(<1, 2, 3>)} \]

Yes.

This is not the number 3! This is the string of one character “3”. Numeric strings are *not* evaluated to the corresponding numbers.

Here, we assert a fact about a list of three *symbols* that represent natural numbers.
We can perform simple queries on lists.

```
P?> less_than_4(<1, 2, ?x>)
Yes.
?x = 3
P?> more?
No.
```
PyGic: Lists

We can perform simple queries on lists.

P?> less_than_4(<1, 2, 3>)
Yes.
P?> less_than_4(<1, ?what>)
No.
P?> less_than_4(?what)
Yes.
?what = <1, 2, 3>
PyGic: Lists

Why are lists denoted by angle brackets (<>)?

PyGic lists are (internally) represented as recursive lists (RLists).

Many of our queries (and later, rules) will deal with the first and the rest of our lists separately.
We use the “split” (|) character to separate the first of the list from the rest of the list.

P?> less_than_4(⟨?first | ?rest⟩)
Yes.
?first = 1
?rest = ⟨2, 3⟩

Remember that these lists are recursively defined, so the list ⟨1, 2, 3⟩ is actually a pair whose first element is 1, and whose second element (the “rest”) is the list ⟨2, 3⟩.
**PyGIC: Lists**

We assert the following fact:

\[ P \rightarrow \text{fact favorite_things(\langle raindrops, roses, whiskers \rangle)} \]

What will the interpreter respond to the following queries:

\[ P \rightarrow \text{favorite_things(\langle ?\text{first} | ?\text{rest} \rangle)} \]

\[ P \rightarrow \text{favorite_things(\langle ?\text{first}, ?\text{second} | ?\text{rest} \rangle)} \]

\[ P \rightarrow \text{favorite_things(\langle ?\text{first}, ?\text{second}, ?\text{third} \rangle)} \]

\[ P \rightarrow \text{favorite_things(\langle ?f, ?s, ?t | ?\text{fourth} \rangle)} \]

\[ P \rightarrow \text{favorite_things(\langle ?\text{first} \rangle)} \]
We assert the following fact:
\[
P?> \text{fact favorite\_things(}<\text{raindrops}, \text{roses}, \text{whiskers}>)
\]

What will the interpreter respond to the following queries:
\[
P?> \text{favorite\_things(}<?\text{first} | ?\text{rest}>)
?\text{first} = \text{raindrops}, \text{rest} = <\text{roses}, \text{whiskers}>
\]
\[
P?> \text{favorite\_things(}<?\text{first}, \text{second} | ?\text{rest}>)
?\text{first} = \text{raindrops}, \text{second} = \text{roses}, \text{rest} = <\text{whiskers}>
\]
\[
P?> \text{favorite\_things(}<?\text{first}, \text{second}, \text{third}>)
?\text{first} = \text{raindrops}, \text{second} = \text{roses}, \text{third} = \text{whiskers}
\]
\[
P?> \text{favorite\_things(}<?\text{f}, \text{s}, \text{t} | ?\text{fourth}>)
?\text{f} = \text{raindrops}, \text{s} = \text{roses}, \text{t} = \text{whiskers}, \text{fourth} = \text{<>}
\]
\[
P?> \text{favorite\_things(}<?\text{first}>)
\]
No.
PyGic: Rules

Great! We can now assert facts and run queries on those facts.

PyGic will then attempt to match the pattern of the query against all of the facts, and will show those that match the pattern.

But, PyGic is more than a simple pattern matcher!
PyGic can also *infer* a fact from other facts through user-defined *rules*.

P??> rule grandfather(?person, ?grandson):

- ?person is the grandfather of ?grandson if...
- ?person is the father of ?son and...
- father(?person, ?son)
- ?son is the father of ?grandson.
- father(?son, ?grandson)
PYGIC: RULES

These rules allow the interpreter to infer other facts that we did not initially specify:

\[
P ?> \text{grandfather}(james, \ ?who)\]

Yes.

\(?who = james\_sirius\)
PYGIC: RULES

These rules allow the interpreter to infer other facts that we did not initially specify:

P?> grandfather(?who, ?grandson)
Yes.
?who = james
?grandson = james_sirius
PYGIC: RULES

Notice that all we did was define **what** a grandfather-grandson relationship was in terms of two father-son relationships.

We did not tell the interpreter **how** to determine a grandfather-grandson relationship.

PyGic uses *logical inference* to establish new facts.
PYGIC: RULES

P?> rule grandfather(?person, ?grandson):
... father(?person, ?son)
... father(?son, ?grandson)

The conclusion is true only if the hypotheses are true.

= 

Can variables be replaced with values such that the hypotheses are true? If so, the conclusion is true too.
PYGIC: RULES

A hypothesis is *true* if there is a fact that matches it, *or* there is a true conclusion for another rule that matches it.
**PyGic: Rules**

If the interpreter can find values for variables

?person, ?son, and ?grandson,

such that the two hypotheses

father(?person, ?son)  
father(?son, ?grandson)

match facts or conclusions of other rules, *then* the conclusion

grandfather(?person, ?grandson)

is true.

If the hypotheses match the conclusions of other rules, the truth value for the rules is checked recursively.
PYGIC: RULES

Remember that these are not functions!
They cannot be composed.

P?> rule grandfather(?person, ?grandson):
  ...
  father(?person, father(?grandson))

The above rule will not work.
There is no fact or rule that matches the hypothesis.
The Solution to Oversleeping.

Introducing the greatest alarm clock. The Puppy Alarm!

When the alarm sounds, an adorable puppy will appear somewhere in your room!

The puppy will disappear in 30 seconds UNLESS you get out of bed and pet the cute puppy!

Puppy!

Order now! Kitten alarm also available.

http://www.bonkersworld.net/the-solution-to-oversleeping/
http://invisiblebread.com/2012/05/the-best-alarm/
PyGic: Rules for Lists

We can also define rules for lists.

For example, say we want to check if two (flat) lists are equal.

What are some facts we know about equal lists?
**PyGic: Rules for Lists**

**Fact 1:**
The empty list is only equal to itself.

\[
P?> \text{fact equal_lists(},<>\text{, }<>\text{)}
\]

A fact, by the way, is equivalent to a rule with True in the body:

\[
P?> \text{rule equal_lists(},<>\text{, }<>\text{):}
\]

... True

True is a PyGic keyword that is, well, true.
PYGIC: RULES FOR LISTS

Fact 2:
Two lists are equal if their first elements are equal, and if the rest of their elements are equal.

P? rule equal_lists(<<x | ?rest1>, <<x | ?rest2>>):
... equal_lists(?rest1, ?rest2)

The same variable is used in two places. A list can therefore only match if the first elements have the same value.
PyGic: Rules for Lists

We can now run queries as before:

P?> equal_lists(<1, 2, 3>, <1, 2, 3>)
Yes.
P?> equal_lists(<1, 2, 3>, <1, 2>)
No.
**PyGic: Rules for Lists**

But, we can now also find variables that *satisfy* our queries!

P?> equal_lists(<1, 2, 3>, <1, 2, ?what>)
Yes.
?what = 3
P?> equal_lists(<1, 2, 3>, ?what)
?what = <1, 2, 3>
PyGic: Rules for Lists

In the previous example, all we had to do was specify facts and rules about the equality of lists.

The interpreter then used these rules to not only check if two lists were equal, but also infer what variables could make two lists equal.

We will see how this works in more detail tomorrow: today, we will focus more on solving problems with logic programming.
Another example: how do we check if an element is a member of a list?

What are some facts that we know about an element that is a member of a list?
If an element is a member of a list, it must either be the first element, or it must be a member of the rest of the list.
PYGIC: RULES FOR LISTS

If an element is a member of a list, it must either be the first element:

P?> fact member(?x, <-?x | _>)

or it must be a member of the rest of the list:

P?> rule member(?x, <- | ?rest>):
... member(?x, ?rest)
PYGIC: RULES FOR LISTS

We can run queries as before:

P?> member(2, <2, 3, 4>)
Yes.
P?> member(2, <3, 4>)
No.
P?> member(3, <>)
No.
**PyGlic: Rules for Lists**

We can also find values for variables that satisfy our queries!

P?> member(?what, <2, 3>)
Yes.
?what = 2
P?> more?
Yes.
?what = 3
P?> more?
No.
PyGic: Rules for Lists (Practice)

We want to append one list to another:

P?> append(<1, 2, 3>, <4, 5>, <1, 2, 3, 4, 5>)
Yes.
P?> append(<1, 2, 3>, <4, 5>, ?what)
Yes.
?what = <1, 2, 3, 4, 5>
What are two facts that we can state about the problem?

**Fact 1:** Appending the empty list to any other list gives us the __________.

**Fact 2:** Appending one list to another is equivalent to adding the first element of the first list to the result of _____________________________.

What facts or rules should we then define?
What are two facts that we can state about the problem?

Fact 1: Appending the empty list to any other list gives us the other list.

Fact 2: Appending one list to another is equivalent to adding the first element of the first list to the result of appending the rest of the first list to the second list.

What facts or rules should we then define?
**PyGic: Rules for Lists (Practice)**

P??> fact append(<> , ?z , ?z)
P??> rule append(<?>x | ?u> , ?v ,<?>x | ?w>):
...
... append(?u , ?v , ?w)
PyGic: Rules for Lists (Practice)

We can now run append “backwards”.

P?> append(<1, 2, 3>, ?what, <1, 2, 3, 4, 5>)
Yes.
?what = <4, 5>
**PyGic: Other Useful Statements**

- `listing(rule_name=None)`
  Prints the rules with the same name as that provided. If no rule name is provided, all rules in the database are printed.

- `clear(rule_name=None)`
  Removes the rules with the given name. If no rule name is provided, all rules in the database are removed.
CONCLUSION

• Declarative programming is a programming paradigm where the computer is presented with certain facts and rules about a problem, from which the computer must then deduce the solution.

• Logic programming is a type of declarative programming that uses logical inference.

• This is in contrast to imperative programming, where the computer is told how to do a problem.

• Preview: What is happening under the hood?
