1 Introduction

SQL is an example of a declarative programming language. Statements do not describe computations directly, but instead describe the desired result of some computation. It is the role of the query interpreter of the database system to plan and perform a computational process to produce such a result.

In SQL, data is organized into tables. A table has a fixed number of named columns. A row of the table represents a single data record and has one value for each column. For example, we have a table named `records` that stores information about the employees at a small company\(^1\). Each of the eight rows represents an employee.

<table>
<thead>
<tr>
<th>Name</th>
<th>Division</th>
<th>records Title</th>
<th>Salary</th>
<th>Supervisor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ben Bitdiddle</td>
<td>Computer</td>
<td>Wizard</td>
<td>60000</td>
<td>Oliver Warbucks</td>
</tr>
<tr>
<td>Alyssa P Hacker</td>
<td>Computer</td>
<td>Programmer</td>
<td>40000</td>
<td>Ben Bitdiddle</td>
</tr>
<tr>
<td>Cy D Fect</td>
<td>Computer</td>
<td>Programmer</td>
<td>35000</td>
<td>Ben Bitdiddle</td>
</tr>
<tr>
<td>Lem E Tweakit</td>
<td>Computer</td>
<td>Technician</td>
<td>25000</td>
<td>Ben Bitdiddle</td>
</tr>
<tr>
<td>Louis Reasoner</td>
<td>Computer</td>
<td>Programmer Trainee</td>
<td>30000</td>
<td>Alyssa P Hacker</td>
</tr>
<tr>
<td>Oliver Warbucks</td>
<td>Administration</td>
<td>Big Wheel</td>
<td>150000</td>
<td>Oliver Warbucks</td>
</tr>
<tr>
<td>Eben Scrooge</td>
<td>Accounting</td>
<td>Chief Accountant</td>
<td>75000</td>
<td>Oliver Warbucks</td>
</tr>
<tr>
<td>Robert Cratchet</td>
<td>Accounting</td>
<td>Scrivener</td>
<td>18000</td>
<td>Eben Scrooge</td>
</tr>
</tbody>
</table>

2 Creating Tables

We can use a SELECT statement to create tables. The following statement creates a table with a single row, with columns named “first” and “last”:

```
sqlite> SELECT "Ben" AS first, "Bitdiddle" AS last;
Ben|Bitdiddle
```

Given two tables with the same number of columns, we can combine their rows into a larger table with UNION:

```
sqlite> SELECT "Ben" AS first, "Bitdiddle" AS last UNION
    ...> SELECT "Louis", "Reasoner";
Ben|Bitdiddle
Louis|Reasoner
```

\(^1\)Example adapted from Structure and Interpretation of Computer Programs
To save a table, use `CREATE TABLE` and a name. Here we’re going to create the table of employees from the previous section and assign it to the name `records`:

```
sqlite> CREATE TABLE records AS
    ...> SELECT "Ben Bitdiddle" AS name, "Computer" AS division,
    ...>     "Wizard" AS title, 60000 AS salary,
    ...>     "Oliver Warbucks" AS supervisor UNION
    ...> SELECT "Alyssa P Hacker", "Computer",
    ...>     "Programmer", 40000, "Ben Bitdiddle" UNION ... ;
```

We can SELECT specific values from an existing table using a `FROM` clause. This query creates a table with two columns, with a row for each row in the `records` table:

```
sqlite> SELECT name, division FROM records;
Alyssa P Hacker|Computer
Ben Bitdiddle|Computer
Cy D Fect|Computer
Eben Scrooge|Accounting
Lem E Tweakit|Computer
Louis Reasoner|Computer
Oliver Warbucks|Administration
Robert Cratchet|Accounting
```

The special syntax `SELECT *` will select all columns from a table. It’s an easy way to print the contents of a table.

```
sqlite> SELECT * FROM records;
Alyssa P Hacker|Computer|Programmer|40000|Ben Bitdiddle
Ben Bitdiddle|Computer|Wizard|60000|Oliver Warbucks
Cy D Fect|Computer|Programmer|35000|Ben Bitdiddle
Eben Scrooge|Accounting|Chief Accountant|75000|Oliver Warbucks
Lem E Tweakit|Computer|Technician|25000|Ben Bitdiddle
Louis Reasoner|Computer|Programmer Trainee|30000|Alyssa P Hacker
Oliver Warbucks|Administration|Big Wheel|150000|Oliver Warbucks
Robert Cratchet|Accounting|Scrivener|18000|Eben Scrooge
```

We can choose which columns to show in the first part of the `SELECT`, we can filter out rows using a `WHERE` clause, and sort the resulting rows with an `ORDER BY` clause. In general the syntax is:

```
SELECT [columns] FROM [tables]
    WHERE [condition] ORDER BY [criteria];
```

For instance, the following statement lists all information about employees with the “Programmer” title.

```
sqlite> SELECT * FROM records WHERE title = "Programmer";
Alyssa P Hacker|Computer|Programmer|40000|Ben Bitdiddle
Cy D Fect|Computer|Programmer|35000|Ben Bitdiddle
```

The following statement lists the names and salaries of each employee under the accounting division, sorted in descending order by their salaries.
sqlite> SELECT name, salary FROM records
...> WHERE division = "Accounting" ORDER BY -salary;
Eben Scrooge | 75000
Robert Cratchet | 18000

Note that all valid SQL statements must be terminated by a semicolon (;). Additionally, you can split up your statement over many lines and add as much whitespace as you want, much like Scheme. But keep in mind that having consistent indentation and line breaking does make your code a lot more readable to others (and your future self)!

Questions

Our tables:

    records: Name Division Title Salary Supervisor

2.1 Write a query that outputs the names of employees that Oliver Warbucks directly supervises.

2.2 Write a query that outputs all information about employees that supervise themselves.

2.3 Write a query that outputs the names of all employees with salary greater than 50,000 in alphabetical order.

3 Joins

Suppose we have another table meetings which records the divisional meetings.

<table>
<thead>
<tr>
<th>Division</th>
<th>Day</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accounting</td>
<td>Monday</td>
<td>9am</td>
</tr>
<tr>
<td>Computer</td>
<td>Wednesday</td>
<td>4pm</td>
</tr>
<tr>
<td>Administration</td>
<td>Monday</td>
<td>11am</td>
</tr>
<tr>
<td>Administration</td>
<td>Wednesday</td>
<td>4pm</td>
</tr>
</tbody>
</table>

Data are combined by joining multiple tables together into one, a fundamental operation in database systems. There are many methods of joining, all closely related, but we will focus on just one method (the inner join) in this class.

When tables are joined, the resulting table contains a new row for each combination of rows in the input tables. If two tables are joined and the left table has $m$ rows and the right table has $n$ rows, then the joined table will have $mn$ rows. Joins are expressed in SQL by separating table names by commas in the FROM clause of a SELECT statement.
sqlite> SELECT name, day FROM records, meetings;
Ben Bitdiddle | Monday
Ben Bitdiddle | Wednesday
...
Alyssa P Hacker | Monday
...

Tables may have overlapping column names, and so we need a method for disambiguating column names by table. A table may also be joined with itself, and so we need a method for disambiguating tables. To do so, SQL allows us to give aliases to tables within a FROM clause using the keyword AS and to refer to a column within a particular table using a dot expression. In the example below we find the name and title of Louis Reasoner’s supervisor.

sqlite> SELECT b.name, b.title FROM records AS a, records AS b
    ...> WHERE a.name = "Louis Reasoner" AND
    ...> a.supervisor = b.name;
Alyssa P Hacker | Programmer

Questions

Our tables:

<table>
<thead>
<tr>
<th>records:</th>
<th>Name</th>
<th>Division</th>
<th>Title</th>
<th>Salary</th>
<th>Supervisor</th>
</tr>
</thead>
<tbody>
<tr>
<td>meetings:</td>
<td>Division</td>
<td>Day</td>
<td>Time</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

3.1 Write a query that outputs the meeting days and times of all employees directly supervised by Oliver Warbucks.

3.2 Write a query that outputs the names of employees whose supervisor is in a different division.
3.3 Write a query that outputs the names of all pairs of employees that have a meeting at the same time. Make sure that if A|B appears in your output, B|A does not appear as well (A|A and B|B should additionally not appear).

3.4 (Extra question) Will the statement above filter out all redundant output in all cases? Why or why not?

4 Aggregation

So far, we have joined and manipulated individual rows using SELECT statements. But we can also perform aggregation operations over multiple rows with the same SELECT statements.

We can use the MAX, MIN, COUNT, and SUM functions to retrieve more information from our initial tables.

If we wanted to find the name and salary of the employee who makes the most money, we might say

```
sqlite> SELECT name, MAX(salary) FROM records;
Oliver Warbucks|150000
```

Using the special COUNT(*) syntax, we can count the number of rows in our table to see the number of employees at the company.

```
sqlite> SELECT COUNT(*) FROM RECORDS;
9
```

These commands can be performed on specific sets of rows in our table by using the GROUP BY [column name] clause. This clause takes all of the rows that have the same value in column name and groups them together.

We can find the minimum salary earned in each division of the company.

```
sqlite> SELECT division, MIN(salary) FROM records GROUP BY division;
Computer|25000
Administration|25000
Accounting|18000
```
These groupings can be additionally filtered by the HAVING clause. In contrast to the WHERE clause, which filters out rows, the HAVING clause filters out entire groups.

To find all titles that are held by more than one person, we say

```
sqlite> SELECT title FROM records GROUP BY title HAVING count(*) > 1;
```

**Questions**

Our tables:

```
records: Name Division Title Salary Supervisor
meetings: Division Day Time
```

4.1 Write a query that outputs each supervisor and the sum of salaries of all the employees they supervise.

4.2 Write a query that outputs the days of the week for which fewer than 5 employees have a meeting. You may assume no department has more than one meeting on a given day.

4.3 Write a query that outputs all divisions for which there is more than one employee, and all pairs of employees within that division have a salary less than 100,000.
5 Modifying Tables

Tables don’t need to begin fully formed, it’s possible to update them after creation!
We’ll also introduce this alternative syntax for creating a table, which creates an
empty table with the given columns:

```
CREATE TABLE [table]([column1], [column2] DEFAULT [val], ...);
```

The optional `DEFAULT` keyword denotes default values for a given column if they’re
not specified. This will be relevant when we insert new elements into our table. To
add a new table entries, use the `INSERT INTO` statement:

```
INSERT INTO [table] ([column1], [column2], ...)
VALUES ([value1], [value2], ...), ([value1], [value2], ...);
```

A couple of notes:

- If a value is specified for each column of the table, you don’t need to specify
column names. This is because each value matches up with a column, so
there’s no ambiguity.

- For columns where a value is not specified, the default value will be used if
available. If not a default value was not provided, that column in the new row
will be left empty!

Here’s an example of insertion into an empty table:

```
sqlite> CREATE TABLE dogs(name, age, phrase DEFAULT "woof");
sqlite> INSERT INTO dogs(name, age) VALUES ("Fido", 1), ("Sparky", 2);
sqlite> INSERT INTO dogs VALUES ("Lassie", 2, "I'll save you!"), ("Floofy", 3);
Error: all VALUES must have the same number of terms
sqlite> SELECT * FROM dogs;
Fido|1|woof
Sparky|2|woof
Lassie|2|I'll save you!
Floofy|3|Much doge
```

The `INSERT INTO` statement can also insert a table returned by a `SELECT` statement,
in which case the syntax is:

```
INSERT INTO [table] ([column1], [column2], ...)
SELECT ...
```

We can update certain existing entries in a table using `UPDATE`:

```
UPDATE [table] SET [column1] = [value1], [column2] = [value2], ... WHERE [condition];
```

All rows matching the condition will have their columns updated. If no condition
is specified, all rows will be updated! We can also remove certain entries in a table
using `DELETE`:

```
DELETE FROM [table] WHERE [condition];
```
Just like with UPDATE, if no condition is specified, all rows will be deleted! Here's an example using all of the above:

```sql
sqlite> UPDATE dogs SET age=age+1; -- If condition isn't specified, every row is updated
sqlite> SELECT * FROM dogs;
Fido|2|woof
Sparky|3|woof
Lassie|3|I'll save you!
Floofy|4|Much doge
```

```sql
sqlite> UPDATE dogs SET phrase = "bark" WHERE age=2;
sqlite> SELECT * FROM dogs WHERE age=2;
Fido|2|bark
sqlite> DELETE FROM dogs WHERE age=3;
sqlite> SELECT * FROM dogs;
Fido|2|bark
Floofy|4|Much doge
```

Finally, we can delete an entire table using the DROP TABLE [table] statement. In this example, the .schema statement shows us a list of the current tables, along with their column names.

```sql
sqlite> .schema
CREATE TABLE dogs(name, age, phrase DEFAULT "woof");
sqlite> DROP TABLE dogs;
sqlite> .schema
sqlite> -- Nothing displayed above
```

Questions

Our tables:

```plaintext
dogs: Name   Age   Phrase, DEFAULT="woof"
```

5.1 What would SQL display? Keep track of the contents of the table after every statement below. Write Error if you think a statement would cause an error.

```sql
sqlite> SELECT * FROM dogs;
Fido|1|woof
Sparky|2|woof
Lassie|2|I'll save you!
Floofy|3|Much doge
```

```sql
sqlite> INSERT INTO dogs(age, name) VALUES ("Rover", 3);
sqlite> SELECT * FROM dogs;
```
sqlite> UPDATE dogs SET name=age, age=name WHERE name=3;
sqlite> SELECT * FROM dogs;

sqlite> UPDATE dogs SET phrase="Hi there!" WHERE name LIKE "F%";
sqlite> SELECT * FROM dogs;

sqlite> DELETE FROM dogs WHERE age < 3;
sqlite> SELECT * FROM dogs;

sqlite> INSERT INTO dogs VALUES ("Spot", 2), ("Buster", 4);

sqlite> INSERT INTO dogs(name, phrase) VALUES ("Spot", "bark"), ("Buster", "barkbark");
sqlite> SELECT * FROM dogs;

sqlite> INSERT INTO dogs(name, age) SELECT name, phrase from dogs where age = 3;
sqlite> DELETE FROM dogs WHERE phrase != "woof";
sqlite> SELECT * FROM dogs;
6 Extra Questions

Use the following table called courses for the questions below:

<table>
<thead>
<tr>
<th>Professor</th>
<th>Course</th>
<th>Semester</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dan Garcia</td>
<td>CS 61C</td>
<td>Sp19</td>
</tr>
<tr>
<td>John DeNero</td>
<td>CS 61A</td>
<td>Fa18</td>
</tr>
<tr>
<td>Dan Garcia</td>
<td>CS 10</td>
<td>Fa18</td>
</tr>
<tr>
<td>Josh Hug</td>
<td>CS 61B</td>
<td>Sp18</td>
</tr>
<tr>
<td>John DeNero</td>
<td>CS 61A</td>
<td>Sp18</td>
</tr>
<tr>
<td>John DeNero</td>
<td>CS 61A</td>
<td>Fa17</td>
</tr>
<tr>
<td>Paul Hilfinger</td>
<td>CS 61A</td>
<td>Fa17</td>
</tr>
<tr>
<td>Paul Hilfinger</td>
<td>CS 61A</td>
<td>Sp17</td>
</tr>
<tr>
<td>John DeNero</td>
<td>Data 8</td>
<td>Sp17</td>
</tr>
<tr>
<td>Josh Hug</td>
<td>CS 61B</td>
<td>Sp17</td>
</tr>
<tr>
<td>Satish Rao</td>
<td>CS 70</td>
<td>Sp17</td>
</tr>
<tr>
<td>Nicholas Weaver</td>
<td>CS 61C</td>
<td>Sp17</td>
</tr>
<tr>
<td>Gerald Friedland</td>
<td>CS 61C</td>
<td>Sp17</td>
</tr>
</tbody>
</table>

6.1 Create a table called num_taught that contains three columns: professor, the course they taught, and the number of times they taught each course.

6.2 Write a query that outputs two professors and a course if they have taught that course the same number of times. You may use the num_taught table you created in the previous question.

6.3 Write a query that outputs two professors if they co-taught (taught the same course at the same time) the same course more than once.
