Recreation

Given that

\[ \log(1 + x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \ldots \]

why is it not the case that

\[
\begin{align*}
\log 2 &= 1 - 1/2 + 1/3 - 1/4 + 1/5 - 1/6 + 1/7 - 1/8 + 1/9 - \ldots \\
&= (1 + 1/3 + 1/5 + 1/7 + 1/9 + \ldots) - (1/2 + 1/4 + 1/6 + 1/8 + \ldots) \\
&= (1 + 1/3 + 1/5 + 1/7 + 1/9 + \ldots) + (1/2 + 1/4 + 1/6 + 1/8 + \ldots) \\
&\quad - 2(1/2 + 1/4 + 1/6 + 1/8 + \ldots) \\
&= (1 + 1/2 + 1/3 + 1/4 + \ldots) - (1 + 1/2 + 1/3 + 1/4 + \ldots) \\
&= 0?
\end{align*}
\]
Basic Idea.

- **Function-based programs** are organized primarily around the functions (methods, etc.) that do things. Data structures (objects) are considered separate.

- **Object-based programs** are organized around the types of objects that are used to represent data; methods are grouped by type of object.

- Simple banking-system example:
Philosophy

- Idea (from 1970s and before): An abstract data type is
  - a set of possible values (a domain), plus
  - a set of operations on those values (or their containers).
- In IntList, for example, the domain was a set of pairs: (head, tail), where head is an int and tail is a pointer to an IntList.
- The IntList operations consisted only of assigning to and accessing the two fields (head and tail).
- In general, we prefer a purely procedural interface, where the functions (methods) do everything—no outside access to the internal representation (i.e., instance variables).
- That way, implementor of a class and its methods has complete control over behavior of instances.
- In Java, the preferred way to write the “operations of a type” is as instance methods.
You Saw It All (Maybe) in CS61A: The Account Class

class Account:
    balance = 0
    def __init__(self, balance0):
        self.balance = balance0
    def deposit(self, amount):
        self.balance += amount
        return self.balance
    def withdraw(self, amount):
        if self.balance < amount:
            raise ValueError(
                "Insufficient funds"
            )
        else:
            self.balance -= amount
            return self.balance

myAccount = Account(1000)
print(myAccount.balance)
myAccount.deposit(100)
myAccount.withdraw(500)

public class Account {
    public int balance;
    public Account(int balance0) {
        this.balance = balance0;
    }
    public int deposit(int amount) {
        balance += amount; return balance;
    }
    public int withdraw(int amount) {
        if (balance < amount)
            throw new IllegalStateException("Insufficient funds");
        else balance -= amount;
        return balance;
    }
}

Account myAccount = new Account(1000);
print(myAccount.balance)
myAccount.deposit(100);
myAccount.withdraw(500);
(define-class (account balance0)
  (instance-vars (balance 0))
  (initialize
   (set! balance balance0)))

(method (deposit amount)
  (set! balance (+ balance amount))
  balance)

(method (withdraw amount)
  (if (< balance amount)
    (error "Insufficient funds")
    (begin
      (set! balance (- balance amount))
      balance)))

(define my-account
  (instantiate account 1000))
(ask my-account 'balance)
(ask my-account 'deposit 100)
(ask my-account 'withdraw 500)

public class Account {
  public int balance;
  public Account(int balance0) {
    balance = balance0;
  }
  public int deposit(int amount) {
    balance += amount; return balance;
  }
  public int withdraw(int amount) {
    if (balance < amount)
      throw new IllegalStateException("Insufficient funds");
    else balance -= amount;
    return balance;
  }
}

Account myAccount = new Account(1000);
myAccount.balance
myAccount.deposit(100);
myAccount.withdraw(500);
The Pieces

- **Class declaration** defines a new type of object, i.e., new type of structured container.

- **Instance variables** such as balance are the simple containers within these objects (fields or components).

- **Instance methods**, such as deposit and withdraw are like ordinary (static) methods that take an invisible extra parameter (called this).

- The **new** operator creates (instantiates) new objects, and initializes them using constructors.

- **Constructors** such as the method-like declaration of Account are special methods that are used only to initialize new instances. They take their arguments from the **new** expression.

- **Method selection** picks methods to call. For example,
  
  ```java
  myAccount.deposit(100)
  ```

  tells us to call the method named deposit that is defined for the object pointed to by myAccount.
Getter Methods

- Slight problem with Java version of Account: anyone can assign to the balance field
- This reduces the control that the implementor of Account has over possible values of the balance.
- Solution: allow public access only through methods:

```
public class Account {
    private int _balance;
    ...
    public int balance() { return _balance; }
    ...
}
```
- Now Account._balance = 1000000 is an error outside Account.
- (I use the convention of putting '$_' at the start of private instance variables to distinguish them from local variables and non-private variables. Could actually use balance for both the method and the variable, but please don't.)
Class Variables and Methods

• Suppose we want to keep track of the bank’s total funds.

• This number is not associated with any particular Account, but is common to all—it is class-wide. In Java, “class-wide” ≡ static.

```java
public class Account {
    ... 
    private static int _funds = 0;
    public int deposit(int amount) {
        _balance += amount;
        _funds += amount;   // or this._funds or Account._funds
        return _balance;
    }
    public static int funds() {
        return _funds;  // or Account._funds
    }
    ...  // Also change withdraw.
}
```

• From outside, can refer to either Account.funds() or to myAccount.funds() (same thing).
instance methods

- instance method such as

```java
int deposit(int amount) {
  _balance += amount;
  _funds += amount;
  return balance;
}
```

behaves sort of like a static method with hidden argument:

```java
static int deposit(final Account this, int amount) {
  this._balance += amount;
  _funds += amount;
  return this._balance;
}
```

- note: just explanatory: Not real Java (not allowed to declare 'this'). (final is real Java; means "can't change once set.")
/** (Fictional) equivalent of deposit instance method. */
static int deposit(final Account this, int amount) {
    this._balance += amount;
    _funds += amount;
    return this._balance;
}

• Likewise, the instance-method call myAccount.deposit(100) is like a call on this fictional static method:

    Account.deposit(myAccount, 100);

• Inside a real instance method, as a convenient abbreviation, one can leave off the leading 'this.' on field access or method call if not ambiguous. (Unlike Python)
'Instance' and 'Static' Don't Mix

- Since real static methods don't have the invisible this parameter, makes no sense to refer directly to instance variables in them:

```java
public static int badBalance(Account A) {
    int x = A._balance; // This is OK
    // (A tells us whose balance)
    return _balance; // WRONG! NONSENSE!
}
```

- Reference to _balance here equivalent to this._balance,

- But this is meaningless (whose balance?)

- However, it makes perfect sense to access a static (class-wide) field or method in an instance method or constructor, as happened with _funds in the deposit method.

- There's only one of each static field, so don't need to have a 'this' to get it. Can just name the class (or use no qualification inside the class, as we've been doing).
Constructors

- To completely control objects of some class, you must be able to set their initial contents.
- A constructor is a kind of special instance method that is called by the `new` operator right after it creates a new object, as if

\[ L = \text{new} \text{IntList}(1, \text{null}) \implies \begin{cases} \text{tmp} = \text{pointer to } 0 \\ \text{tmp} . \text{IntList}(1, \text{null)}; \\ L = \text{tmp}; \end{cases} \]
Multiple Constructors and Default Constructors

- **All** classes have constructors. In the absence of any explicit constructor, get *default constructor*, as if you had written:

  ```java
  public class Foo {
    public Foo() {
    }
  }
  ```

- **Multiple overloaded** constructors possible, and they can use each other (although the syntax is odd):

  ```java
  public class IntList {
    public IntList(int head, IntList tail) {
      this.head = head; this.tail = tail;
    }
    
    public IntList(int head) {
      this(head, null); // Calls first constructor.
    }
    
    ...  
  }
  ```
Constructors and Instance Variables

- Instance variables initializations are moved inside constructors that don't start with `this(...)`.

```java
class Foo {
    int x = 5;

    Foo(int y) {
        DoStuff(y);
    }

    Foo() {
        this(42);
    }
}

class Foo {
    int x;

    Foo(int y) {
        x = 5;
        DoStuff(y);
    }

    Foo() {
        this(0); // Assigns to x
    }
}
```
### Summary: Java vs. Python

<table>
