Today:

- Pseudo-random Numbers (Chapter 11)
- What use are random sequences?
- What are “random sequences”?
- Pseudo-random sequences.
- How to get one.
- Relevant Java library classes and methods.
- Random permutations.
Why Random Sequences?

- Choose statistical samples
- Simulations
- Random algorithms
- Cryptography:
  - Choosing random keys
  - Generating streams of random bits (e.g., stream ciphers encrypt messages by xor'ing reproducible streams of pseudo-random bits with the bits of the message.)
- And, of course, games
What Is a “Random Sequence”?

• How about: “a sequence where all numbers occur with equal frequency”?
  - Like 1, 2, 3, 4, …?

• Well then, how about: “an unpredictable sequence where all numbers occur with equal frequency?”
  - Like 0, 0, 0, 1, 1, 2, 2, 2, 2, 3, 4, 4, 0, 1, 1, 1,…?

• Besides, what is wrong with 0, 0, 0, 0, … anyway? Can’t that occur by random selection?
Pseudo-Random Sequences

- Even if definable, a “truly” random sequence is difficult for a computer (or human) to produce.
- For most purposes, need only a sequence that satisfies certain statistical properties, even if deterministic.
- Sometimes (e.g., cryptography) need sequence that is hard or impractical to predict.
- **Pseudo-random sequence**: deterministic sequence that passes some given set of statistical tests.
- For example, look at lengths of runs: increasing or decreasing contiguous subsequences.
- Unfortunately, statistical criteria to be used are quite involved. For details, see Knuth.
Generating Pseudo-Random Sequences

• Not as easy as you might think.
• Seemingly complex jumbling methods can give rise to bad sequences.
• *Linear congruential method* is a simple method used by Java:

\[
\begin{align*}
X_0 &= \text{arbitrary seed} \\
X_i &= (aX_{i-1} + c) \mod m, \quad i > 0
\end{align*}
\]

• Usually, \( m \) is large power of 2.
• For best results, want \( a \equiv 5 \mod 8 \), and \( a, c, m \) with no common factors.
• This gives generator with a *period of* \( m \) (length of sequence before repetition), and reasonable *potency* (measures certain dependencies among adjacent \( X_i \)).
• Also want bits of \( a \) to “have no obvious pattern” and pass certain other tests (see Knuth).
• Java uses \( a = 25214903917, c = 11, m = 2^{48} \), to compute 48-bit pseudo-random numbers. It’s good enough for many purposes, but not *cryptographically secure*.
What Can Go Wrong (I)?

- Short periods, many impossible values: E.g., $a$, $c$, $m$ even.
- Obvious patterns. E.g., just using lower 3 bits of $X_i$ in Java’s 48-bit generator, to get integers in range 0 to 7. By properties of modular arithmetic,

$$X_i \mod 8 = (25214903917X_{i-1} + 11 \mod 2^{48}) \mod 8$$
$$= (5(X_{i-1} \mod 8) + 3) \mod 8$$

so we have a period of 8 on this generator; sequences like

$$0, 1, 3, 7, 1, 2, 7, 1, 4, \ldots$$

are impossible. This is why Java doesn’t give you the raw 48 bits.
What Can Go Wrong (II)?

Bad potency leads to bad correlations.

- The infamous IBM generator RANDU: $c = 0, a = 65539, m = 2^{31}$.
- When RANDU is used to make 3D points: $(X_i/S, X_{i+1}/S, X_{i+2}/S)$, where $S$ scales to a unit cube, . . .
- . . . points will be arranged in parallel planes with voids between. So “random points” won’t ever get near many points in the cube:

Additive Generators

• Additive generator:

\[
X_n = \begin{cases} 
\text{arbitrary value,} & n < 55 \\
(X_{n-24} + X_{n-55}) \mod 2^e, & n \geq 55
\end{cases}
\]

• Other choices than 24 and 55 possible.

• This one has period of \(2^f(2^{55} - 1)\), for some \(f < e\).

• Simple implementation with circular buffer:

\[
i = (i+1) \mod 55; \\
X[i] += X[(i+31) \mod 55]; \quad // \text{Why +31 (55-24) instead of -24?}
\]

\[
\text{return } X[i]; \quad /* \text{modulo } 2^{32} */
\]

• where \(X[0 \ldots 54]\) is initialized to some “random” initial seed values.
Cryptographic Pseudo-Random Number Generators

- The simple form of linear congruential generators means that one can predict future values after seeing relatively few outputs.

- Not good if you want unpredictable output (think on-line games involving money or randomly generated keys for encrypting your web traffic.)

- A cryptographic pseudo-random number generator (CPRNG) has the properties that
  - Given $k$ bits of a sequence, no polynomial-time algorithm can guess the next bit with better than 50% accuracy.
  - Given the current state of the generator, it is also infeasible to reconstruct the bits it generated in getting to that state.
Cryptographic Pseudo-Random Number Generator

Example

• Start with a good block cipher—an encryption algorithm that encrypts blocks of \( N \) bits (not just one byte at a time as for Enigma). AES is an example.

• As a seed, provide a key, \( K \), and an initialization value \( I \).

• The \( j^{\text{th}} \) pseudo-random number is now \( E(K, I + j) \), where \( E(x, y) \) is the encryption of message \( y \) using key \( x \).
### Adjusting Range and Distribution

- **Given** raw sequence of numbers, $X_i$, from above methods in range (e.g.) 0 to $2^{48}$, how to get uniform random integers in range 0 to $n - 1$?

- **If** $n = 2^k$, is easy: use top $k$ bits of next $X_i$ (bottom $k$ bits not as "random")

- **For** other $n$, be careful of slight biases at the ends. For example, if we compute $X_i/(2^{48}/n)$ using all integer division, and if $(2^{48}/n)$ gets rounded down, then you can get $n$ as a result (which you don’t want).

- **If** you try to fix that by computing $(2^{48}/(n - 1))$ instead, the probability of getting $n - 1$ will be wrong.
Adjusting Range (II)

- To fix the bias problems when \( n \) does not evenly divide \( 2^{48} \), Java throws out values after the largest multiple of \( n \) that is less than \( 2^{48} \):

```java
/** Random integer in the range 0 .. n-1, n>0. */
int nextInt(int n) {
    long X = next random long (0 ≤ X < 2^{48});
    if (n is \( 2^k \) for some \( k \))
        return top \( k \) bits of X;

    int MAX = largest multiple of n that is < 2^{48};
    while (X \(_i >= MAX\))
        X = next random long (0 ≤ X < 2^{48});
    return X \(_i / (MAX/n)\);
}
```
Arbitrary Bounds

• How to get arbitrary range of integers \((L \text{ to } U)\)?

• To get random float, \(x\) in range \(0 \leq x < d\), compute

\[
\text{return } d \times \text{nextInt}(1 << 24) / (1 << 24);
\]

• Random double a bit more complicated: need two integers to get enough bits.

\[
\begin{align*}
\text{long bigRand} &= ((\text{long}) \text{nextInt}(1 << 26) << 27) + (\text{long}) \text{nextInt}(1 << 27);
\text{return } d \times \text{bigRand} / (1L \times 53);
\end{align*}
\]
Generalizing: Other Distributions

- Suppose we have some desired probability distribution function, and want to get random numbers that are distributed according to that distribution. How can we do this?

- Example: the normal distribution:

\[ P(Y \leq X) \]

- Curve is the desired probability distribution. \( P(Y \leq X) \) is the probability that random variable \( Y \) is \( \leq X \).
Other Distributions

**Solution:** Choose \( y \) uniformly between 0 and 1, and the corresponding \( x \) will be distributed according to \( P \).

\[
P(X \leq Y)
\]
Java Classes

- Math.random(): random double in [0..1).
- Class java.util.Random: a random number generator with constructors:
  - Random() generator with “random” seed (based on time).
  - Random(seed) generator with given starting value (reproducible).
- Methods
  - next(k) k-bit random integer
  - nextInt(n) int in range [0..n).
  - nextLong() random 64-bit integer.
  - nextBoolean(), nextFloat(), nextDouble() Next random values of other primitive types.
  - nextGaussian() normal distribution with mean 0 and standard deviation 1 (“bell curve”).
- Collections.shuffle(L, R) for list R and Random R permutes L randomly (using R).
Shuffling

- A **shuffle** is a random permutation of some sequence.

- **Obvious dumb technique for sorting** $N$-element list:
  - Generate $N$ random numbers
  - Attach each to one of the list elements
  - Sort the list using random numbers as keys.

- **Can do quite a bit better:**

```java
void shuffle(List L, Random R) {
    for (int i = L.size(); i > 0; i -= 1)
        swap element i-1 of L with element R.nextInt(i) of L;
}
```

- **Example:**

<table>
<thead>
<tr>
<th>Swap items</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>Swap items</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>A♣</td>
<td>2♣</td>
<td>3♣</td>
<td>A♥</td>
<td>2♥</td>
<td>3♥</td>
<td>3 ↔ 3</td>
<td>A♣</td>
<td>3♥</td>
<td>2♥</td>
<td>A♥</td>
<td>3♣</td>
<td>2♣</td>
</tr>
<tr>
<td>5 ↔ 1</td>
<td>A♣</td>
<td>3♥</td>
<td>3♣</td>
<td>A♥</td>
<td>2♥</td>
<td>2♣</td>
<td>2 ↔ 0</td>
<td>2♥</td>
<td>3♥</td>
<td>A♣</td>
<td>A♥</td>
<td>3♣</td>
<td>2♣</td>
</tr>
<tr>
<td>4 ↔ 2</td>
<td>A♣</td>
<td>3♥</td>
<td>2♥</td>
<td>A♥</td>
<td>3♣</td>
<td>2♣</td>
<td>1 ↔ 0</td>
<td>3♥</td>
<td>2♥</td>
<td>A♣</td>
<td>A♥</td>
<td>3♣</td>
<td>2♣</td>
</tr>
</tbody>
</table>
Random Selection

• Same technique would allow us to select $N$ items from list:

```cpp
/** Permute L and return sublist of K>=0 randomly
 * chosen elements of L, using R as random source. */
List select(List L, int k, Random R) {
    for (int i = L.size(); i+k > L.size(); i -= 1)
        swap element i-1 of L with element
            R.nextInt(i) of L;
    return L.sublist(L.size()-k, L.size());
}
```

• Not terribly efficient for selecting random sequence of $K$ distinct integers from $[0..N)$, with $K \ll N$. 
Alternative Selection Algorithm (Floyd)

/** Random sequence of K distinct integers
 * from 0..N-1, 0<=K<=N. */
IntList selectInts(int N, int K, Random R)
{
    IntList S = new IntList();

    for (int i = N-K; i < N; i += 1) {
        // All values in S are < i
        int s = R.randInt(i+1); // 0 <= s <= i < N
        if (s == S.get(j) for some j)
            // Insert value i (which can’t be there
            // yet) after the s (i.e., at a random
            // place other than the front)
            S.add(j+1, i);
        else
            // Insert random value s at front
            S.add(0, s);
    }
    return S;
}

<table>
<thead>
<tr>
<th>i</th>
<th>s</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>4</td>
<td>[4]</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>[2, 4]</td>
</tr>
<tr>
<td>7</td>
<td>5</td>
<td>[5, 2, 4]</td>
</tr>
<tr>
<td>8</td>
<td>5</td>
<td>[5, 8, 2, 4]</td>
</tr>
<tr>
<td>9</td>
<td>4</td>
<td>[5, 8, 2, 4, 9]</td>
</tr>
</tbody>
</table>

Example

selectRandomIntegers(10, 5, R)
