CS61B Lecture #16: Complexity
What Are the Questions?

• Cost is a principal concern throughout engineering:
  “An engineer is someone who can do for a dime what any fool can do for a dollar.”

• Cost can mean
  - Operational cost (for programs, time to run, space requirements).
  - Development costs: How much engineering time? When delivered?
  - Maintenance costs: Upgrades, bug fixes.
  - Costs of failure: How robust? How safe?

• Is this program fast enough? Depends on:
  - For what purpose;
  - For what input data.

• How much space (memory, disk space)?
  - Again depends on what input data.

• How will it scale, as input gets big?
Enlightening Example

Problem: Scan a text corpus (say $10^8$ bytes or so), and find and print the 20 most frequently used words, together with counts of how often they occur.

- Solution 1 (Knuth): Heavy-Duty data structures
  - Hash Trie implementation, randomized placement, pointers galore, several pages long.

- Solution 2 (Doug McIlroy): UNIX shell script:
  \[
  \text{tr} -c -s '[:alpha:]' '[\n*]' < FILE | \n  \text{sort} | \n  \text{uniq} -c | \n  \text{sort} -n -r -k 1,1 | \n  \text{sed} 20q
  \]

- Which is better?
  - #1 is much faster,
  - but #2 took 5 minutes to write and processes 100MB in $\approx 50$ sec.
  - I pick #2.

- In very many cases, almost anything will do: Keep It Simple.
Cost Measures (Time)

- **Wall-clock or execution time**
  - You can do this at home:
    ```
    time java FindPrimes 1000
    ```
  - Advantages: easy to measure, meaning is obvious.
  - Appropriate where time is critical (real-time systems, e.g.).
  - Disadvantages: applies only to specific data set, compiler, machine, etc.

- **Dynamic statement counts** of # of times statements are executed:
  - Advantages: more general (not sensitive to speed of machine).
  - Disadvantages: doesn’t tell you actual time, still applies only to specific data sets.

- **Symbolic execution times:**
  - That is, *formulas* for execution times as functions of input size.
  - Advantages: applies to all inputs, makes scaling clear.
  - Disadvantage: practical formula must be approximate, may tell very little about actual time.
Asymptotic Cost

- Symbolic execution time lets us see *shape* of the cost function.
- Since we are approximating anyway, pointless to be precise about certain things:
  - *Behavior on small inputs*:
    - Can always pre-calculate some results.
    - Times for small inputs not usually important.
    - Often more interested in *asymptotic behavior* as input size becomes very large.
  - *Constant factors* (as in “off by factor of 2”):
    - Just changing machines causes constant-factor change.
- How to abstract away from (i.e., ignore) these things?
Handy Tool: Order Notation

- Idea: Don’t try to produce specific functions that specify size, but rather *families of functions with similarly behaved magnitudes*.

- Then say something like “$f$ is bounded by $g$ if it is in $g$’s family.”

- For any function $g(x)$, the functions $2g(x)$, $0.5g(x)$, or for any $K > 0$, $K \cdot g(x)$, all have the same “shape”. So put all of them into $g$’s family.

- Any function $h(x)$ such that $h(x) = K \cdot g(x)$ for $x > M$ (for some constant $M$) has $g$’s shape “except for small values.” So put all of these in $g$’s family.

- For upper limits, throw in all functions whose absolute value is everywhere $\leq$ some member of $g$’s family. Call this set $O(g)$ or $O(g(n))$.

- Or, for lower limits, throw in all functions whose absolute values is everywhere $\geq$ some member of $g$’s family. Call this set $\Omega(g)$.

- Finally, define $\Theta(g) = O(g) \cap \Omega(g)$—the set of functions *bracketed in magnitude by* two members of $g$’s family.
Big Oh

- **Goal:** Specify bounding from above.

\[ M = 1 \]

- Here, \( f(x) \leq 2g(x) \) as long as \( x > 1 \),

- So \( f(x) \) is in \( g \)’s “bounded-above family,” written

\[ f(x) \in O(g(x)) \],

- … even though (in this case) \( f(x) > g(x) \) everywhere.
Big Omega

• Goal: Specify bounding from below:

\[ g(x) \]

\[ f'(x) \in \Omega(g(x)) \]

• Here, \( f'(x) \geq \frac{1}{2}g(x) \) as long as \( x > 1 \),

• So \( f'(x) \) is in \( g \)'s “bounded-below family,” written

\[ f'(x) \in \Omega(g(x)) \]

• ... even though \( f(x) < g(x) \) everywhere.
Big Theta

- In the two previous slides, we not only have \( f(x) \in O(g(x)) \) and \( f'(x) \in \Omega(g(x)) \),...
- ...but also \( f(x) \in \Omega(g(x)) \) and \( f'(x) \in O(g(x)) \).
- We can summarize this all by saying \( f(x) \in \Theta(g(x)) \) and \( f'(x) \in \Theta(g(x)) \).
Aside: Various Mathematical Pedantry

• Technically, if I am going to talk about $O(\cdot)$, $\Omega(\cdot)$ and $\Theta(\cdot)$ as sets of functions, I really should write, for example,

$$f \in O(g) \quad \text{instead of} \quad f(x) \in O(g(x))$$

• In effect, $f(x) \in O(g(x))$ is short for $\lambda x. f(x) \in O(\lambda x. g(x))$.

• The standard notation outside this course, in fact, is $f(x) = O(g(x))$, but personally, I think that’s a serious abuse of notation.
How We Use Order Notation

• Elsewhere in mathematics, you’ll see $O(\ldots)$, etc., used generally to specify bounds on functions.

• For example,

$$\pi(N) = \Theta\left( \frac{N}{\ln N} \right)$$

which I would prefer to write

$$\pi(N) \in \Theta\left( \frac{N}{\ln N} \right)$$

(Here, $\pi(N)$ is the number of primes less than or equal to $N$.)

• Also, you’ll see things like

$$f(x) = x^3 + x^2 + O(x) \quad \text{(or } f(x) \in x^4 + x^2 + O(x)),$$

meaning that $f(x) = x^3 + x^2 + g(x)$ where $g(x) \in O(x)$.

• For our purposes, the functions we will be bounding will be cost functions: functions that measure the amount of execution time or the amount of space required by a program or algorithm.
Why It Matters

• Computer scientists often talk as if constant factors didn't matter at all, only the difference of $\Theta(N)$ vs. $\Theta(N^2)$.

• In reality they do matter, but at some point, constants always get swamped.

Some Intuition on Meaning of Growth

- How big a problem can you solve in a given time?
- In the following table, left column shows time in microseconds to solve a given problem as a function of problem size \( N \).
- Entries show the size of problem that can be solved in a second, hour, month (31 days), and century, for various relationships between time required and problem size.
- \( N = \text{problem size} \).

<table>
<thead>
<tr>
<th>Time ((\mu\text{sec})) for problem size (N)</th>
<th>1 second</th>
<th>Max (N) Possible in 1 hour</th>
<th>Max (N) Possible in 1 month</th>
<th>Max (N) Possible in 1 century</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
Using the Notation

• Can use this order notation for any kind of real-valued function.
• We will use them to describe cost functions. Example:

```java
/** Find position of X in list L, or -1 if not found. */
int find(List L, Object X) {
    int c;
    for (c = 0; L != null; L = L.next, c += 1)
        if (X.equals(L.head)) return c;
    return -1;
}
```

• Choose representative operation: number of `.equals` tests.
• If \( N \) is length of \( L \), then loop does at most \( N \) tests: worst-case time is \( N \) tests.
• In fact, total \# of instructions executed is roughly proportional to \( N \) in the worst case, so can also say worst-case time is \( O(N) \), regardless of units used to measure.
• Use \( N > M \) provision (in defn. of \( O(\cdot) \)) to ignore empty list.
Be Careful

• It’s also true that the worst-case time is $O(N^2)$, since $N \in O(N^2)$ also: Big-Oh bounds are loose.

• The worst-case time is $\Omega(N)$, since $N \in \Omega(N)$, but that does not mean that the loop always takes time $N$, or even $K \cdot N$ for some $K$.

• Instead, we are just saying something about the function that maps $N$ into the largest possible time required to process any array of length $N$.

• To say as much as possible about our worst-case time, we should try to give a $\Theta$ bound: in this case, we can: $\Theta(N)$.

• But again, that still tells us nothing about best-case time, which happens when we find $x$ at the beginning of the loop. Best-case time is $\Theta(1)$. 
Effect of Nested Loops

• Nested loops often lead to polynomial bounds:

```java
for (int i = 0; i < A.length; i += 1)
    for (int j = 0; j < A.length; j += 1)
        if (i != j && A[i] == A[j])
            return true;
return false;
```

• Clearly, time is $O(N^2)$, where $N = A.length$. Worst-case time is $\Theta(N^2)$.

• Loop is inefficient though:

```java
for (int i = 0; i < A.length; i += 1)
    for (int j = i+1; j < A.length; j += 1)
        if (A[i] == A[j]) return true;
return false;
```

• Now worst-case time is proportional to

$$N - 1 + N - 2 + \ldots + 1 = N(N - 1)/2 \in \Theta(N^2)$$

(so asymptotic time unchanged by the constant factor).
Recursion and Recurrences: Fast Growth

• Silly example of recursion. In the worst case, both recursive calls happen:

```java
/** True iff X is a substring of S */
boolean occurs(String S, String X) {
    if (S.equals(X)) return true;
    if (S.length() <= X.length()) return false;
    return
        occurs(S.substring(1), X) ||
        occurs(S.substring(0, S.length()-1), X);
}
```

• Define \( C(N) \) to be the worst-case cost of \( \text{occurs}(S,X) \) for \( S \) of length \( N \), \( X \) of fixed size \( N_0 \), measured in \# of calls to \( \text{occurs} \). Then

\[
C(N) = \begin{cases} 
1, & \text{if } N \leq N_0, \\
2C(N - 1) + 1 & \text{if } N > N_0 
\end{cases}
\]

• So \( C(N) \) grows exponentially:

\[
C(N) = 2C(N - 1) + 1 = 2(2C(N - 2) + 1) + 1 = \ldots = 2(\ldots 2 \cdot 1 + 1) + \ldots + 1 = 2^{N-N_0+1} - 1 \in \Theta(2^N)
\]
/** True X iff is an element of S[L .. U]. Assumes
 *  S in ascending order, 0 <= L <= U-1 < S.length. */

boolean isIn(String X, String[] S, int L, int U) {
    if (L > U) return false;
    int M = (L+U)/2;
    int direct = X.compareTo(S[M]);
    if (direct < 0) return isIn(X, S, L, M-1);
    else if (direct > 0) return isIn(X, S, M+1, U);
    else return true;
}

• Here, worst-case time, \( C(D) \), (as measured by \# of calls to \.compareTo\),
depends on size \( D = U - L + 1 \).

• We eliminate \( S[M] \) from consideration each time and look at half the
  rest. Assume \( D = 2^k - 1 \) for simplicity, so:

\[
C(D) = \begin{cases} 
0, & \text{if } D \leq 0, \\
1 + C((D - 1)/2), & \text{if } D > 0.
\end{cases}
\]

\[
= \underbrace{1 + 1 + \ldots + 1}_k + 0
\]
\[
= k = \log(D + 1) \in \Theta(\log D)
\]
Another Typical Pattern: Merge Sort

\[
\text{List sort}(\text{List } L) \begin{cases} 
\quad \text{if } (L.\text{length()} < 2) \text{ return } L; \\
\quad \text{Split } L \text{ into } L_0 \text{ and } L_1 \text{ of about equal size;} \\
\quad L_0 = \text{sort}(L_0); \quad L_1 = \text{sort}(L_1); \\
\quad \text{return Merge of } L_0 \text{ and } L_1
\end{cases}
\]

\[
\text{Merge ("combine into a single ordered list") takes time proportional to size of its result.}
\]

- Assuming that size of \( L \) is \( N = 2^k \), worst-case cost function, \( C(N) \), counting just merge time (which is proportional to \# items merged):

\[
C(N) = \begin{cases} 
0, & \text{if } N < 2; \\
2C(N/2) + N, & \text{if } N \geq 2.
\end{cases}
\]

\[
= 2(2C(N/4) + N/2) + N \\
= 4C(N/4) + N + N \\
= 8C(N/8) + N + N + N \\
= N \cdot 0 + \underbrace{N + N + \ldots + N}_{k=\lg N} \\
= N \lg N
\]

- In general, can say it's \( \Theta(N \lg N) \) for arbitrary \( N \) (not just \( 2^k \)).
