

Lecture 3 – Introduction to the C Programming Language (pt 1)

2007-01-22

There is one handout today at the front and back of the room!

Lecturer SOE Dan Garcia

www.cs.berkeley.edu/~ddgarcia

HP overcomes Moore's Law? ⇒

Their design: "field programmable nanowire interconnect (FPNI)" uses a technique that "will enable chip makers to pack eight times as many transistors as is currently possible on a standard 45nm field programmable gate array (FPGA) chip."

Number review...

- We represent "things" in computers as particular bit patterns: $N \text{ bits} \Rightarrow 2^N$
- Decimal for human calculations, binary for computers, hex to write binary more easily
- 1's complement - mostly abandoned

- 2's complement universal in computing: cannot avoid, so learn

Overflow: numbers ∞ ; computers finite, errors!

Has there been an update to ANSI C?

- Yes! It's called the "C99" or "C9x" std
 - You need "gcc -std=c99" to compile

References

<http://en.wikipedia.org/wiki/C99>
http://home.tiscalinet.ch/t_wolf/tw/c/c9x_changes.html

Highlights

- Declarations anywhere, like Java (#15)
- Java-like // comments (to end of line) (#10)
- Variable-length non-global arrays (#33)
- <inttypes.h>: explicit integer types (#38)
- <stdbool.h> for boolean logic def's (#35)
- restrict keyword for optimizations (#30)

Disclaimer

- **Important:** You will not learn how to fully code in C in these lectures! You'll still need your C reference for this course.

- K&R is a must-have reference
 - Check online for more sources
- "JAVA in a Nutshell," O'Reilly.
 - Chapter 2, "How Java Differs from C"
- Brian Harvey's course notes
 - On class website

Compilation : Overview

C **compilers** take C and convert it into an **architecture specific** machine code (string of 1s and 0s).

- Unlike Java which converts to architecture independent bytecode.
- Unlike most Scheme environments which interpret the code.
- These differ mainly in **when** your program is converted to machine instructions.
- For C, generally a 2 part process of **compiling** .c files to .o files, then **linking** the .o files into executables

CS61C L03 Introduction to C (pt 1) (10)

Garcia, Spring 2007 © UC

Compilation : Advantages

- **Great run-time performance:** generally much faster than Scheme or Java for comparable code (because it optimizes for a given architecture)
- **OK compilation time:** enhancements in compilation procedure (`Makefiles`) allow only modified files to be recompiled

CS61C L03 Introduction to C (pt 1) (11)

Garcia, Spring 2007 © UC

Compilation : Disadvantages

- All compiled files (including the executable) are **architecture specific**, depending on *both* the CPU type and the operating system.
- Executable must be **rebuilt** on each new system.
 - Called “**porting your code**” to a new architecture.
- The “change→compile→run [repeat]” iteration cycle is slow

C vs. Java™ Overview (1/2)

Java	C
• Object-oriented (OOP)	• No built-in object abstraction. Data separate from methods.
• “Methods”	• “Functions”
• Class libraries of data structures	• C libraries are lower-level
• Automatic memory management	• Manual memory management
	• Pointers

CS61C L03 Introduction to C (pt 1) (13)

Garcia, Spring 2007 © UC

C vs. Java™ Overview (2/2)

Java	C
• High memory overhead from class libraries	• Low memory overhead
• Relatively Slow	• Relatively Fast
• Arrays initialize to zero	• Arrays initialize to garbage
• Syntax: <code>/* comment */ // comment System.out.print</code>	• Syntax: * <code>/* comment */ // comment printf</code>

*You need newer C compilers to allow Java style comments, or just use C99

C Syntax: Variable Declarations

- Very similar to Java, but with a few minor but important differences
- All variable declarations must go before they are used (at the beginning of the block)*
- A variable may be initialized in its declaration.
- Examples of declarations:

```
• correct: {  
    int a = 0, b = 10;  
    ...  
• Incorrect:* for (int i = 0; i < 10; i++)
```

*C99 overcomes these limitations

C Syntax: True or False?

- What evaluates to FALSE in C?
 - 0 (integer)
 - NULL (pointer: more on this later)
 - no such thing as a Boolean*
- What evaluates to TRUE in C?
 - **everything else...**
 - (same idea as in scheme: only `#f` is false, everything else is true!)

*Boolean types provided by C99's `stdbool.h`

Pointers

- How to change a variable pointed to?
 - Use dereference * operator on left of =

Pointers and Parameter Passing

- Java and C pass parameters “by value”
 - procedure/function/method gets a copy of the parameter, so changing the copy cannot change the original

```
void addOne (int x) {  
    x = x + 1;  
}  
  
int y = 3;  
addOne (y);
```

y is still = 3

Pointers and Parameter Passing

- How to get a function to change a value?

```
void addOne (int *p) {  
    *p = *p + 1;  
}  
  
int y = 3;
```

```
addOne (&y);
```

y is now = 4

Pointers

- Pointers are used to point to **any** data type (int, char, a struct, etc.).
- Normally a pointer can only point to one type (int, char, a struct, etc.).
 - void * is a type that can point to anything (generic pointer)
 - Use sparingly to help avoid program bugs... and security issues... and a lot of other bad things!

Peer Instruction Question

```
void main(); {  
    int *p, x=5, y; // init  
    y = *(p = &x) + 10;  
    int z;  
    flip-sign(p);  
    printf("x=%d,y=%d,p=%d\n", x,y,p);  
}  
flip-sign(int *n){*n = -(*n)}
```

How many syntax/logic errors?

#Errors
0
1
2
3
4
5
6
7
8
9

And in conclusion...

- All declarations go at the beginning of each function.
- Only 0 and NULL evaluate to FALSE.
- All data is in memory. Each memory location has an address to use to refer to it and a value stored in it.
- A **pointer** is a C version of the address.
 - * “follows” a pointer to its value
 - & gets the address of a value
