CS 61C More C & Memory Management

Spring 2010 Scott Beamer (cs61c-ta)

Quick Array Problem

Fill in the function to make it compute the dot product of a • b
int dotProduct(int[] a, int[] b, int length) {

}

Dynamic Memory Allocation Summary

- int sizeof(datatype) returns the number of bytes needed to hold datatype
- void* malloc(int numBytes) returns address of dynamically allocated block that is numBytes long, or returns 0 if it can't satisfy that request
- void free (void *ptr) releases the memory that ptr points to

Summary of struct

- Composes simpler data types to make data structures
- Can get an element by: *structInstanceName.elementName*
- If passed by a pointer, ptrName->elementName instead of (*ptrName).elementName

Summary of typedef

- typedef replaceWith searchFor;
- For declarations, replaces searchFor with replaceWith

Linked List Example

```
typedef char *String;
typedef struct Node {
    String value;
    struct Node *next;
} NodeStruct;
typedef NodeStruct *List;
List cons (String s, List list) {
    List node = (List) malloc(sizeof(NodeStruct));
    node->value = (String) malloc (strlen(s) + 1);
    strcpy(node->value, s);
    node->next = list;
    return node;
}
```

Summary of union

- Used to make more general data types (syntax is like struct)
- Only 1 type is valid at a given time and it is programmer's responsibility to know which
- Often another variable is used to hold which type is there

```
union Number {
    float fVal;
    double dVal;
} realNum;

// let numType hold realNum's type
if (numType == FLOAT)
realNum.fVal = 3.14f;
else if (numType == DOUBLE)
realNum.dVal = 3.14;
```

General Linked List Problem

Change the declaration from the Linked List Example to handle int's in addition to Strings by using unions. Make a function that sums the values of the elements assuming they are ints.

```
int sumList(List list) {
```
