This homework is due September 4, 2017, at 23:59.  
Self-grades are due September 7, 2017, at 23:59.

Submission Format
Your homework submission should consist of two files.

- **hw1.pdf**: A single PDF file that contains all of your answers (any handwritten answers should be scanned) as well as your IPython notebook saved as a PDF.
  
  If you do not attach a PDF of your IPython notebook, you will not receive credit for problems that involve coding. Make sure that your results and your plots are visible.

- **hw1.ipynb**: A single IPython notebook with all of your code in it.
  
  In order to receive credit for your IPython notebook, you must submit both a “printout” and the code itself.

Submit each file to its respective assignment on Gradescope.

1. Administrivia

   If you want to be eligible for midterm clobbering, what do you need to do?

   **Solution:**
   
   You need to (1) attend at least 75% of the discussions (not including discussions in the first week of class) and (2) either submit no more than 1 late assignment (whether this is the homework itself or the self-grade for that homework) or contribute by posting/answering relevant (as judged by the course staff) technical questions on Piazza at least 10 times over the course of the semester.

2. (PRACTICE) Finding Charges from Potential Measurements

   **Solution:** #modeling #matrixNotation

   We have three point charges $Q_1$, $Q_2$, and $Q_3$ whose positions are known, and we want to determine their charges. In order to do that, we take three potential measurements $U_1$, $U_2$, and $U_3$ at three different locations. The locations of the charges and potentials are shown in Figure[1].

   For the purpose of this problem, the following equation is true:

   \[ U = k \frac{Q}{r} \]

   at a point $r$ meters away (for some fixed physical constant $k$; this problem does not require its numerical value).

   Furthermore, the potential contributions from different point charges add up linearly. For example, in the setup of Figure[1] the potential measured at point $U_2$ is

   \[ U_2 = k \frac{Q_1}{1} + k \frac{Q_2}{\sqrt{2}} + k \frac{Q_3}{1}. \]
Given that the actual potential measurements in the setup of Figure 1 are

\[ U_1 = k \frac{4 + 3\sqrt{5} + \sqrt{10}}{2\sqrt{5}}, \]
\[ U_2 = k \frac{2 + 4\sqrt{2}}{\sqrt{2}}, \]
\[ U_3 = k \frac{4 + \sqrt{5} + 3\sqrt{10}}{2\sqrt{5}}, \]

write the system of linear equations relating the potentials to charges. Solve the system to find the charges \( Q_1, Q_2, Q_3 \). You may use your IPython notebook to solve the system.

**IPython hint:** For constants \( a_i, b_i, c_i, y_i \), you can solve the system of linear equations

\[
\begin{align*}
    a_1 x_1 + a_2 x_2 + a_3 x_3 &= y_1 \\
    b_1 x_1 + b_2 x_2 + b_3 x_3 &= y_2 \\
    c_1 x_1 + c_2 x_2 + c_3 x_3 &= y_3
\end{align*}
\]

in IPython with the following code:

```python
import numpy as np
a = np.array([[a1, a2, a3],
              [b1, b2, b3],
              [c1, c2, c3]])
b = np.array([y1, y2, y3])
x = np.linalg.solve(a, b)
```

The square root of a number \( a \) can be written as \( \text{np.sqrt}(a) \) in IPython.

**Solution:**
Let us denote the distance to the $i$th potential measurement point from the $j$th source as $r_{ij}$. By using the Pythagorean theorem (formula for the length of the hypotenuse of a right triangle), we get the following:

\[
\begin{align*}
& r_{1,1} = \sqrt{2}, & r_{1,2} = \sqrt{5}, & r_{1,3} = 2, \\
& r_{2,1} = 1, & r_{2,2} = \sqrt{2}, & r_{2,3} = 1, \\
& r_{3,1} = 2, & r_{3,2} = \sqrt{5}, & r_{3,3} = \sqrt{2}.
\end{align*}
\]

Then, the potentials $U_1$, $U_2$ and $U_3$ can be expressed as

\[
\begin{align*}
& k \left( \frac{Q_1}{\sqrt{2}} + \frac{Q_2}{\sqrt{5}} + \frac{Q_3}{2} \right) = U_1, \\
& k \left( \frac{Q_1}{\sqrt{2}} + \frac{Q_2}{\sqrt{2}} + Q_3 \right) = U_2, \\
& k \left( \frac{Q_1}{2} + \frac{Q_2}{\sqrt{5}} + \frac{Q_3}{\sqrt{2}} \right) = U_3.
\end{align*}
\]

Plugging in the values of $U_1$, $U_2$ and $U_3$ and dividing by $k$, we get the following system of equations:

\[
\begin{align*}
& \frac{Q_1}{\sqrt{2}} + \frac{Q_2}{\sqrt{5}} + \frac{Q_3}{2} = \frac{4 + 3\sqrt{5} + \sqrt{10}}{2\sqrt{5}}, \\
& Q_1 + \frac{Q_2}{\sqrt{2}} + Q_3 = \frac{2 + 4\sqrt{2}}{\sqrt{2}}, \\
& \frac{Q_1}{2} + \frac{Q_2}{\sqrt{5}} + \frac{Q_3}{\sqrt{2}} = \frac{4 + \sqrt{5} + 3\sqrt{10}}{2\sqrt{5}}.
\end{align*}
\]

The system can be solved by the following IPython code:

```python
import numpy as np
r11 = np.sqrt(2); r12 = np.sqrt(5); r13 = 2
r21 = 1; r22 = np.sqrt(2); r23 = 1
r31 = 2; r32 = np.sqrt(5); r33 = np.sqrt(2)
y1 = (4 + 3*np.sqrt(5) + np.sqrt(10)) / (2*np.sqrt(5))
y2 = (2 + 4*np.sqrt(2)) / (np.sqrt(2))
y3 = (4 + np.sqrt(5) + 3*np.sqrt(10)) / (2*np.sqrt(5))
a = np.array([
    [1/r11, 1/r12, 1/r13],
    [1/r21, 1/r22, 1/r23],
    [1/r31, 1/r32, 1/r33]
])
b = np.array([y1, y2, y3])
x = np.linalg.solve(a, b)
print(x)
```

The result is $Q_1 = 1$, $Q_2 = 2$, and $Q_3 = 3$. 

EECS 16A, Fall 2017, Homework 1
3. Sahai’s Optimal Smoothies

Solution: #SystemsOfEquations #GaussianElimination

Sahai’s Optimal Smoothies has a unique way of serving its customers. To ensure the best customer experience, each customer gets a smoothie personalized to his or her tastes. Professor Sahai knows that a lot of customers don’t know what they want, so when the customer walks up to the counter, they are asked to taste four standard smoothies that cover the entire range of flavors found in the smoothies.

Each smoothie is made of $\frac{1}{2}$ cup Greek yogurt, $\frac{1}{8}$ cup vanilla soy milk, $\frac{1}{2}$ cup crushed ice, and 1 cup mystery fruit. The four standard smoothies have the following recipes for the cup of mystery fruit:

<table>
<thead>
<tr>
<th>Fruit [cups]</th>
<th>Banana Berry</th>
<th>Caribbean Passion</th>
<th>Mango-a-go-go</th>
<th>Strawberries Wild</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strawberries</td>
<td>$\frac{1}{3}$</td>
<td>$\frac{1}{3}$</td>
<td>0</td>
<td>$\frac{2}{3}$</td>
</tr>
<tr>
<td>Bananas</td>
<td>$\frac{1}{3}$</td>
<td>$\frac{1}{3}$</td>
<td>$\frac{2}{5}$</td>
<td>$\frac{1}{5}$</td>
</tr>
<tr>
<td>Mangos</td>
<td>0</td>
<td>$\frac{1}{3}$</td>
<td>$\frac{4}{5}$</td>
<td>0</td>
</tr>
<tr>
<td>Blueberries</td>
<td>$\frac{1}{3}$</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Each customer is assumed to have a score (from 0 to 10) for each fruit, and the total score for the smoothie is computed by multiplying the score for a fruit with its proportion in the smoothie. For example, if a customer’s score for strawberries is 6 and bananas is 3, then the total score for the Strawberries Wild smoothie would be $6 \cdot \frac{2}{3} + 3 \cdot \frac{1}{3} = 5$.

After a customer gives a score (from 0 to 10) for each smoothie, Professor Sahai then calculates (on the spot!) how much the customer likes each fruit. Then Professor Sahai blends up a special smoothie that will maximize the customer’s score.

Professor Alon was thirsty after grading midterms, so Professor Alon decided to take a drink break at Sahai’s Optimal Smoothies. Professor Alon walked in and gave the following ratings:

<table>
<thead>
<tr>
<th>Smoothie</th>
<th>Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>Banana Berry</td>
<td>$6\frac{2}{3}$</td>
</tr>
<tr>
<td>Caribbean Passion</td>
<td>$6\frac{2}{3}$</td>
</tr>
<tr>
<td>Mango-a-go-go</td>
<td>$7\frac{2}{3}$</td>
</tr>
<tr>
<td>Strawberries Wild</td>
<td>$5\frac{2}{3}$</td>
</tr>
</tbody>
</table>

(a) What were Professor Alon’s ratings for each fruit? Work this problem out by hand.

Solution:

Using Professor Alon’s ratings, Professor Sahai mentally records the following system of equations:

- **Banana Berry**: $\frac{2}{3} = \frac{1}{3}x_S + \frac{1}{3}x_{Ba} + \frac{1}{3}x_{Bb}$
- **Caribbean Passion**: $\frac{2}{3} = \frac{1}{3}x_S + \frac{1}{3}x_{Ba} + \frac{1}{3}x_M$
- **Mango-a-go-go**: $\frac{2}{5} = \frac{2}{5}x_{Ba} + \frac{3}{5}x_M$
- **Strawberries Wild**: $\frac{2}{3} = \frac{2}{3}x_S + \frac{1}{3}x_{Ba}$

Professor Sahai then multiplies each equation by the denominator of the fraction (in order to make them easier to read):
20 = x_S + x_{Ba} + x_{Bb}
20 = x_S + x_{Ba} + x_{M}
37 = 2x_{Ba} + 3x_{M}
17 = 2x_S + x_{Ba}

Professor Sahai then writes the above equations in matrix form:

\[
\begin{bmatrix}
1 & 1 & 0 & 1 & \vdots & 20 \\
1 & 1 & 1 & 0 & \vdots & 20 \\
0 & 2 & 3 & 0 & \vdots & 37 \\
2 & 1 & 0 & 0 & \vdots & 17
\end{bmatrix}
\begin{bmatrix}
x_S \\
x_{Ba} \\
x_{M} \\
x_{Bb}
\end{bmatrix}
= 
\begin{bmatrix}
20 \\
20 \\
37 \\
17
\end{bmatrix}
\]

and as an augmented matrix:

\[
\begin{bmatrix}
1 & 1 & 0 & 1 & 20 \\
1 & 1 & 1 & 0 & 20 \\
0 & 2 & 3 & 0 & 37 \\
2 & 1 & 0 & 0 & 17
\end{bmatrix}
\]

Professor Sahai then proceeds to row reduce the matrix into reduced row echelon form as follows. (It’s fine if you solved the system of equations by hand a different way. Here, however, we will demonstrate how to do it using Gaussian elimination.)

Noting that there is a 1 in the upper left hand corner, Professor Sahai subtracts Row 1 from Row 2 and 2×Row 1 from Row 4.

Row 2: subtract Row 1
Row 4: subtract 2×Row 1

\[
\begin{bmatrix}
1 & 1 & 0 & 1 & 20 \\
0 & 0 & 1 & -1 & 0 \\
0 & 2 & 3 & 0 & 37 \\
0 & -1 & 0 & -2 & -23
\end{bmatrix}
\]

Since Row 2 has a 0 in the diagonal element, Professor Sahai multiplies Row 4 by −1 and then switches Rows 2 and 4.

Multiply Row 4 by −1
Switch Row 2 and Row 4

\[
\begin{bmatrix}
1 & 1 & 0 & 1 & 20 \\
0 & 1 & 0 & 2 & 23 \\
0 & 2 & 3 & 0 & 37 \\
0 & 0 & 1 & -1 & 0
\end{bmatrix}
\]

Professor Sahai then subtracts Row 2 from Row 1 and 2×Row 2 from Row 3.

Row 1: subtract Row 2
Row 3: subtract 2×Row 2

\[
\begin{bmatrix}
1 & 0 & 0 & -1 & -3 \\
0 & 1 & 0 & 2 & 23 \\
0 & 0 & 3 & -4 & -9 \\
0 & 0 & 1 & -1 & 0
\end{bmatrix}
\]

Professor Sahai then switches Row 3 and Row 4 and then subtracts 3× the new Row 3 from the new Row 4.

Switch Row 3 and Row 4
Row 4: subtract 3×Row 3

\[
\begin{bmatrix}
1 & 0 & 0 & -1 & -3 \\
0 & 1 & 0 & 2 & 23 \\
0 & 0 & 1 & -1 & 0 \\
0 & 0 & 0 & -1 & -9
\end{bmatrix}
\]
Finally, Professor Sahai multiplies Row 4 by \(-1\) and then adds Row 4 to Row 1 and Row 3 and subtracts \(2 \times \text{Row 4}\) from Row 2.

\[
\begin{bmatrix}
1 & 0 & 0 & 6 \\
0 & 1 & 0 & 5 \\
0 & 0 & 1 & 9 \\
0 & 0 & 0 & 9 \\
\end{bmatrix}
\]

Thus, Professor Sahai determines that Professor Alon’s ratings for each fruit are

<table>
<thead>
<tr>
<th>Fruit</th>
<th>Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strawberries</td>
<td>6</td>
</tr>
<tr>
<td>Bananas</td>
<td>5</td>
</tr>
<tr>
<td>Mangos</td>
<td>9</td>
</tr>
<tr>
<td>Blueberries</td>
<td>9</td>
</tr>
</tbody>
</table>

(b) What mystery fruit combination should Professor Sahai put in Professor Alon’s personalized smoothie? What score would Professor Alon give for this smoothie? There may be more than one correct answer.

**Solution:**

*Any* linear combination of mango and blueberry is acceptable as they have equal ratings. More precisely, for any \(0 \leq a \leq 1\), \(a\) cups of mango and \(1 - a\) cups of blueberries. Any such combination will yield a score of 9.

How could you see this? At one level, it is somewhat obvious and it is fine if you said as much — Mangoes and Blueberries are tied for Professor Alon’s favorite fruit, so it doesn’t make a difference if Professor Sahai substitutes one for the other in any quantity. It also doesn’t make sense to substitute a less preferred fruit like Strawberries for Professor Alon’s favorite fruits.

4. The Framingham Risk Score

**Solution:** #SystemsOfEquations

The Framingham risk score estimates the 10-year cardiovascular disease (CVD) risk of an individual. There are multiple factors (predictors) that weigh in the calculation of the Framingham score. For each individual, these factors are: gender, age, total cholesterol, level of high-density lipoprotein (HDL) cholesterol, systolic blood pressure (SBP), whether or not the individual smokes, whether or not the individual is treated for high blood pressure and whether or not the individual is diabetic. For this problem, we will focus on the algorithm that estimates the CVD risk for female individuals who smoke, are not treated for high blood pressure, and are not diabetic.

To calculate the 10-year CVD risk of an individual in the group described above, a score \(R\) is first assigned based on the values of age, total cholesterol, HDL cholesterol, and systolic blood pressure, as follows

\[
R = a \cdot \ln (\text{age (years)}) + b \cdot \ln (\text{total cholesterol (mg/dL)}) + \\
c \cdot \ln (\text{HDL cholesterol (mg/dL)}) + d \cdot \ln (\text{SBP (mm Hg)})
\]

where \(a, b, c\) and \(d\) are constant coefficients and \(\ln (\cdot)\) denotes the natural (base \(e\)) logarithm.

After the score \(R\) is calculated, it is plugged into the following formula in order to obtain the risk \(p\) (in terms of probability) of the individual suffering from a CVD in the next 10 years:

\[
p = 1 - 0.95^{R-25.66}
\]
Table 1: Patient records for 10-year CVD risk assessment.

(Note that there is a double exponent in the expression.)

When the algorithm was first devised, the only copy of the document that reported the coefficients \(a, b, c\) and \(d\) was shredded by mistake by a new intern in the hospital where the research was conducted. The intern needs to find the values of the coefficients from existing records of hospital patients and needs your help to do so.

Throughout the problem, you can approximate any numbers up to the fourth decimal. For example, you can approximate 0.123456789 as 0.12346 and 0.24296 as 0.2430.

(a) The intern dug up some of the records for patients in the study group who fit the criteria of the formula in question. The records are summarized in Table 1. Use these records to devise a system of linear equations where \(a, b, c\) and \(d\) are the unknowns.

Solution:

Given a risk (probability) of CVD \(p\), we can write \(R\) as a function of \(p\) as follows:

\[
p = 1 - 0.95^{e^{R - 25.66}}
\]

\[\iff 0.95^{e^{R - 25.66}} = 1 - p\]

\[\iff e^{R - 25.66} = \log_{0.95} (1 - p)\]

\[\iff R - 25.66 = \ln (\log_{0.95} (1 - p))\]

\[\iff R = \ln (\log_{0.95} (1 - p)) + 25.66\]

Then, for each patient record, we know that

\[
R = a \cdot \ln (\text{age (years)}) + b \cdot \ln (\text{total cholesterol (mg/dL)}) + c \cdot \ln (\text{HDL cholesterol (mg/dL)}) + d \cdot \ln (\text{SBP (mm Hg)})
\]

which is equivalent to

\[
\ln (\log_{0.95} (1 - p)) + 25.66 = a \cdot \ln (\text{age (years)}) + b \cdot \ln (\text{total cholesterol (mg/dL)}) + c \cdot \ln (\text{HDL cholesterol (mg/dL)}) + d \cdot \ln (\text{SBP (mm Hg)})
\]

Therefore, by plugging in the values in Table 1, the system of linear equations is (one equation per patient record):

\[
\begin{align*}
a \cdot \ln(66) + b \cdot \ln(198) + c \cdot \ln(55) + d \cdot \ln(132) &= \ln (\log_{0.95} (1 - 0.1550)) + 25.66 \\
a \cdot \ln(61) + b \cdot \ln(180) + c \cdot \ln(47) + d \cdot \ln(124) &= \ln (\log_{0.95} (1 - 0.1108)) + 25.66 \\
a \cdot \ln(60) + b \cdot \ln(180) + c \cdot \ln(50) + d \cdot \ln(120) &= \ln (\log_{0.95} (1 - 0.0940)) + 25.66 \\
a \cdot \ln(23) + b \cdot \ln(132) + c \cdot \ln(45) + d \cdot \ln(132) &= \ln (\log_{0.95} (1 - 0.0105)) + 25.66
\end{align*}
\]

\[
(1)
\]
You will get full credit if you approximated the values in the system of linear equations (left hand side, right hand side or both) to the following system

\[
\begin{align*}
4.1897 \cdot a + 5.2883 \cdot b + 4.0073 \cdot c + 4.8828 \cdot d &= 26.8489 \\
4.1109 \cdot a + 5.1930 \cdot b + 3.8501 \cdot c + 4.8203 \cdot d &= 26.4883 \\
4.0943 \cdot a + 5.1930 \cdot b + 3.9120 \cdot c + 4.7875 \cdot d &= 26.3147 \\
3.1355 \cdot a + 4.8828 \cdot b + 3.8067 \cdot c + 4.8828 \cdot d &= 24.0791
\end{align*}
\]

(b) Solve the system of linear equations that you devised in part (a) of this problem. For this question, you may use IPython.

Note: The natural logarithm of a number \(x\) (i.e. \(\ln(x)\)) can be written as \(\text{np.log}(x)\) in IPython.

Solution:
The solution of the system of linear equations (1) is

\[a = 2.3099, b = 1.1696, c = -0.6945\text{ and }d = 2.8200.\]

By approximating the right hand side of the system of linear equations (1), the solution would be

\[a = 2.3096, b = 1.1701, c = -0.6945\text{ and }d = 2.8196.\]

By approximating both the left hand side and the right hand side of the system of linear equations, as in Equation (2), the solution would be

\[a = 2.3055, b = 1.1812, c = -0.6960\text{ and }d = 2.8124.\]

Full credit is given to any set of the solutions given above.

A code that solves the system of linear equations in Equation (1) is provided in sol1.ipynb.

As a side note, notice that the coefficient \(c\) has a negative value, indicating that a higher value of the HDL cholesterol would lower the estimated risk of 10-years CVD. This is expected since HDL particles can transport fat molecules out of artery walls – and therefore lowers the risk of arterial clotting, a cause of heart failure. For that reason, HDL cholesterol is often referred to as ‘the good cholesterol’. If you are interested, you can read more about the Framingham heart study at [http://circ.ahajournals.org/content/117/6/743.full](http://circ.ahajournals.org/content/117/6/743.full).

Note: Some of the values in the algorithm were modified from the original study values.

5. Filtering Out The Troll

Solution: #SystemsOfEquations #LinearCombination

You attended a very important public speech and recorded it using a recording device that consists of two directional microphones. However, there was this particular person in the audience who was trolling around. When you went back home to listen to the recording you realized that the two recordings are dominated by the troll and you cannot hear the speech. Fortunately since you had two microphones, you realize that there is a way to combine the two recordings such that trolling is removed. Recollecting the scene, the locations of the speaker and the troll are shown in Figure 2.
The way your recording device works is that each microphone weighs the audio signal depending on the angle of the audio source, relative to the $x$ axis, hence the name *directional microphones*. More specifically, if the audio source is located at an angle of $\theta$, the first microphone will record the audio signal with weight $f_1(\theta) = \cos(\theta)$, and the second microphone will record the audio signal with weight $f_2(\theta) = \sin(\theta)$. For example, an audio source that lies on the $x$ axis will be recorded with the first microphone with weight equal to 1 (since $\cos(0) = 1$), but will not be picked by microphone two (since $\sin(0) = 0$). Note that the weights can also be negative.

Graphically, the directional characteristics of the microphones are given in Figures 3 and 4 (the red and blue colors denote the positive and negative values of the weight, respectively). Putting all of this together, assume that there are two speakers, $A$ and $B$, at angles $\theta$ and $\psi$, respectively. Assume that speaker $A$ produces an audio signal represented by the vector $\vec{a} \in \mathbb{R}^n$. That is, the $i$-th component of $\vec{a}$ is the signal at the $i$-th time step. Similarly, assume speaker $B$ produces an audio signal $\vec{b}$.

Then the first microphone will record the signal

$$\vec{m}_1 = \cos(\theta) \cdot \vec{a} + \cos(\psi) \cdot \vec{b},$$

and the second microphone will record the signal

$$\vec{m}_2 = \sin(\theta) \cdot \vec{a} + \sin(\psi) \cdot \vec{b}.$$
(a) Using the notation above, let the important speaker be speaker $A$ (with signal $\vec{a}$) and let the person trolling be speaker $B$ (with signal $\vec{b}$). Express the recordings of the two microphones $\vec{m}_1$ and $\vec{m}_2$ (i.e. the signals recorded by the first and the second microphones, respectively) as a linear combination of $\vec{a}$ and $\vec{b}$.

Solution:

$$\vec{m}_1 = \cos \left( \frac{\pi}{4} \right) \cdot \vec{a} + \cos \left( \frac{\pi}{6} \right) \cdot \vec{b}$$
$$= \frac{1}{\sqrt{2}} \cdot \vec{a} + \frac{\sqrt{3}}{2} \cdot \vec{b}$$

$$\vec{m}_2 = \sin \left( \frac{\pi}{4} \right) \cdot \vec{a} + \sin \left( -\frac{\pi}{6} \right) \cdot \vec{b}$$
$$= \frac{1}{\sqrt{2}} \cdot \vec{a} - \frac{1}{2} \cdot \vec{b}$$

(b) Recover the important speech $\vec{a}$, as a weighted combination of $\vec{m}_1$ and $\vec{m}_2$. In other words, write $\vec{a} = u \cdot \vec{m}_1 + v \cdot \vec{m}_2$ (where $u$ and $v$ are scalars). What are the values of $u$ and $v$?

Solution:

Solving the system of linear equations yields

$$\vec{a} = \frac{\sqrt{2}}{1 + \sqrt{3}} \cdot (\vec{m}_1 + \sqrt{3} \vec{m}_2).$$

Therefore, the values are $u = \frac{\sqrt{2}}{1 + \sqrt{3}}$ and $v = \frac{\sqrt{6}}{1 + \sqrt{3}}$.

It is fine if you solved this using IPython or by hand using any valid technique. The easiest approach is to subtract the two equations from each other and immediately see that $\vec{b} = \frac{2}{\sqrt{3}+1} (\vec{m}_1 - \vec{m}_2)$. Substituting that back into the second equation and multiplying through by $\sqrt{2}$ gives that $\vec{a} = \sqrt{2} (\vec{m}_2 + \frac{1}{\sqrt{3}+1} (\vec{m}_1 - \vec{m}_2))$ which simplifies to the expression given above.

Notice that subtracting the two from each other is natural given the symmetry of the microphone patterns and the fact that they intersect at the 45 degree line where the important speech is happening.
So we know that the result will only contain the troll. Once we have the troll contribution, we can remove it.

(c) Partial IPython code can be found in `prob1.ipynb`. Complete the code to get a clean signal of the important speech. What does the speaker say? (Optional: Where is the speech taken from?)

*Note:* You may have noticed that the recordings of the two microphones sounded remarkably similar. This means that you could recover the real speech from two “trolled” recordings that sounded almost identical! Leave out the fact that the recordings are actually different, and have some fun with your friends who aren’t lucky enough to be taking EE16A.

**Solution:**

The solution code can be found in `sol1.ipynb`. The speaker says: “All human beings are born free and equal in dignity and rights.” and the speech was taken from the Universal Declaration of Human Rights.

The idea of using multiple microphones to isolate speech is interesting and is increasingly used in practice. Furthermore, similar techniques are used in wireless communication both by cellular systems like LTE and increasingly by WiFi hotspots. (This is why they often have multiple antennas).

**6. Homework Process and Study Group**

Who else did you work with on this homework? List names and student ID’s. (In case of homework party, you can also just describe the group.) How did you work on this homework?

**Solution:**

I worked on this homework with...

I first worked by myself for 2 hours, but got stuck on problem 5, so I went to office hours on...

Then I went to homework party for a few hours, where I finished the homework.

**7. Write Your Own Question And Provide a Thorough Solution.**

Writing your own problems is a very important way to really learn material. The famous “Bloom’s Taxonomy” that lists the levels of learning is: Remember, Understand, Apply, Analyze, Evaluate, and Create. Using what you know to create is the top level. We rarely ask you any homework questions about the lowest level of straight-up remembering, expecting you to be able to do that yourself (e.g. making flashcards). But we don’t want the same to be true about the highest level. As a practical matter, having some practice at trying to create problems helps you study for exams much better than simply counting on solving existing practice problems. This is because thinking about how to create an interesting problem forces you to really look at the material from the perspective of those who are going to create the exams. Besides, this is fun. If you want to make a boring problem, go ahead. That is your prerogative. But it is more fun to really engage with the material, discover something interesting, and then come up with a problem that walks others down a journey that lets them share your discovery. You don’t have to achieve this every week. But unless you try every week, it probably won’t ever happen.
