Assembly Language

• Basic job of a CPU: execute lots of *instructions*.
• Instructions are the primitive operations that the CPU may execute.
• Different CPUs implement different sets of instructions. The set of instructions a particular CPU implements is an *Instruction Set Architecture (ISA)*.
  
  – Examples: ARM, Intel x86, MIPS, RISC-V, IBM/Motorola PowerPC (old Mac), Intel IA64, ...
Instruction Set Architectures

• Early trend was to add more and more instructions to new CPUs to do elaborate operations
  – VAX architecture had an instruction to multiply polynomials!

• RISC philosophy (Cocke IBM, Patterson, Hennessy, 1980s) – Reduced Instruction Set Computing
  – Keep the instruction set small and simple, makes it easier to build fast hardware.
  – Let software do complicated operations by composing simpler ones.
MIPS Architecture

• MIPS – semiconductor company that built one of the first commercial RISC architectures
• We will study the MIPS architecture in some detail in this class (also used in upper division courses CS 152, 162, 164)

• Why MIPS instead of Intel x86?
  – MIPS is simple, elegant. Don’t want to get bogged down in gritty details.
  
  – MIPS widely used in embedded apps, x86 little used in embedded, and more embedded computers than PCs
Assembly Variables: Registers

• Unlike HLL like C or Java, assembly cannot use variables
  – Why not? Keep Hardware Simple

• Assembly Operands are **registers**
  – Limited number of special locations built directly into the hardware
  – Operations can only be performed on these!

• Benefit: Since registers are directly in hardware, they are very fast
  (**faster than 1 ns - light travels 30cm in 1 ns!!!**)
Number of MIPS Registers

• Drawback: Since registers are in hardware, there are a predetermined number of them
  – Solution: MIPS code must be very carefully put together to efficiently use registers

• 32 registers in MIPS
  – Why 32? Smaller is faster, but too small is bad. Goldilocks problem.

• Each MIPS register is 32 bits wide
  – Groups of 32 bits called a word in MIPS
Names of MIPS Registers

• Registers are numbered from 0 to 31
• Each register can be referred to by number or name
• Number references:
  – $0, $1, $2, … $30, $31
• For now:
  – $16 - $23 ➔ $s0 - $s7 (correspond to C variables)
  – $8 - $15 ➔ $t0 - $t7 (correspond to temporary variables)
  – Later will explain other 16 register names
• In general, use names to make your code more readable
C, Java variables vs. registers

• In C (and most High Level Languages) variables declared first and given a type
  • Example: int fahr, celsius;
    char a, b, c, d, e;
• Each variable can ONLY represent a value of the type it was declared as (cannot mix and match int and char variables).
• In Assembly Language, registers have no type; operation determines how register contents are treated
Addition and Subtraction of Integers

• Addition in Assembly
  – Example: \texttt{add \$s0,\$s1,\$s2} (in MIPS)
  – Equivalent to: \( a = b + c \) (in C)
    where C variables \( \leftrightarrow \) MIPS registers are:
    \( a \leftrightarrow \$s0, \ b \leftrightarrow \$s1, \ c \leftrightarrow \$s2 \)

• Subtraction in Assembly
  – Example: \texttt{sub \$s3,\$s4,\$s5} (in MIPS)
  – Equivalent to: \( d = e - f \) (in C)
    where C variables \( \leftrightarrow \) MIPS registers are:
    \( d \leftrightarrow \$s3, \ e \leftrightarrow \$s4, \ f \leftrightarrow \$s5 \)
Addition and Subtraction of Integers

Example 1

• How to do the following C statement?
  \[ \text{a = b + c + d - e;} \]

• Break into multiple instructions
  \[
  \begin{align*}
  &\text{add $t0, $s1, $s2} \# \text{ temp = b + c} \\
  &\text{add $t0, $t0, $s3} \# \text{ temp = temp + d} \\
  &\text{sub $s0, $t0, $s4} \# \text{ a = temp - e}
  \end{align*}
  \]

• A single line of C may break up into several lines of MIPS.

• Notice the use of temporary registers – don’t want to modify the variable registers $s$

• Everything after the hash mark on each line is ignored (comments)
Immediates

• Immediates are numerical constants.
• They appear often in code, so there are special instructions for them.
• Add Immediate:
  \[
  \text{addi } \$s0,\$s1,-10 \quad (\text{in MIPS})
  \]
  \[
  f = g - 10 \quad (\text{in C})
  \]
  where MIPS registers \$s0,\$s1 are associated with C variables \text{f, g}
• Syntax similar to add instruction, except that last argument is a number instead of a register.
  \[
  \text{add } \$s0,\$s1,\$zero \quad (\text{in MIPS})
  \]
  \[
  f = g \quad (\text{in C})
  \]
Overflow in Arithmetic

• Reminder: Overflow occurs when there is a “mistake” in arithmetic due to the limited precision in computers.
• Example (4-bit unsigned numbers):

\[
\begin{array}{c}
15 \\
+ 3 \\
\hline
18
\end{array} \quad \begin{array}{c}
1111 \\
+ 0011 \\
\hline
10010
\end{array}
\]

• But we don’t have room for 5-bit solution, so the solution would be 0010, which is +2, and “wrong”.

13
Overflow handling in MIPS

- Some languages detect overflow (Ada), some don’t (most C implementations)
- MIPS solution is 2 kinds of arithmetic instructions:
  - These cause overflow to be detected
    - add (add)
    - add immediate (addi)
    - subtract (sub)
  - These do not cause overflow detection
    - add unsigned (addu)
    - add immediate unsigned (addiu)
    - subtract unsigned (subu)
- Compiler selects appropriate arithmetic
  - MIPS C compilers produce addu, addiu, subu
Data Transfer: Load from and Store to memory

Processor

Control

Bytes

Data

Input

Output

Processor-Memory Interface

I/O-Memory Interfaces
Memory Addresses are in Bytes

- Lots of data is smaller than 32 bits, but rarely smaller than 8 bits – works fine if everything is a multiple of 8 bits
- 8 bit chunk is called a *byte* (1 word = 4 bytes)
- Memory addresses are really in *bytes*, not words
- Word addresses are 4 bytes apart
  - Word address is same as address of leftmost byte (i.e. Big-endian)
Transfer from Memory to Register

• C code
  
  ```
  int A[100];
  g = h + A[3];
  ```

• Using Load Word (lw) in MIPS:
  
  ```
lw $t0, 12($s3)  # Temp reg $t0 gets A[3]
add $s1, $s2, $t0  # g = h + A[3]
  ```

Note:  
- $s3 – base register (pointer)
- 12 – offset in bytes
Offset must be a constant known at assembly time
Transfer from Register to Memory

• C code

```c
int A[100];
```

• Using Store Word (sw) in MIPS:

```mips
lw  $t0, 12($s3)    # Temp reg $t0 gets A[3]
add $t0, $s2, $t0   # Temp reg $t0 gets h + A[3]
sw  $t0, 40($s3)    # A[10] = h + A[3]
```

Note:  
$s3$ – base register (pointer)  
$12, 40$ – offsets in bytes

$s3+12$ and $s3+40$ must be multiples of 4
Loading and Storing bytes

• In addition to word data transfers (lw, sw), MIPS has byte data transfers:
  – load byte: lb
  – store byte: sb
• Same format as lw, sw
• E.g., lb $s0, 3($s1)
  – contents of memory location with address = sum of “3” + contents of register $s1 is copied to the low byte position of register $s0.

$s0$:  

\[ \begin{array}{cccccccccccc}
\text{xxxx} & \text{xxxx} & \text{xxxx} & \text{xxxx} & \text{xxxx} & \text{xxxx} & \text{xxxx} & \text{xxxx} & \text{xxxx} & \text{xxxx} & \text{xxxx} & \text{xxxx} \\
\end{array} \]

...is copied to “sign-extend”

This bit

byte loaded

zzzz zzzzz
Speed of Registers vs. Memory

• Given that
  – Registers: 32 words (128 Bytes)
  – Memory: Billions of bytes (2 GB to 8 GB on laptop)
• and the RISC principle is...
  – Smaller is faster
• How much faster are registers than memory??
• About 100-500 times faster!
  – in terms of latency of one access
How many hours $h$ on Homework 0?

A: $0 \leq h < 5$
B: $5 \leq h < 10$
C: $10 \leq h < 15$
D: $15 \leq h < 20$
E: $20 \leq h$
Clickers/Peer Instruction

We want to translate \( *x = *y + 1 \) into MIPS
\((x, y\) pointers stored in: \( \$s0 \) \( \$s1 \))

A: \text{addi} \ $s0, $s1, 1

B: \text{lw} \ $s0, 1(\$s1)
    \text{sw} \ $s1, 0(\$s0)

C: \text{lw} \ $t0, 0(\$s1)
    \text{addi} \ $t0, 0, 1
    \text{sw} \ $t0, 0(\$s0)

D: \text{sw} \ $t0, 0(\$s1)
    \text{addi} \ $t0, \$t0, 1
    \text{lw} \ $t0, 0(\$s0)

E: \text{lw} \ $s0, 1(\$t0)
    \text{sw} \ $s1, 0(\$t0)
MIPS Logical Instructions

- Useful to operate on fields of bits within a word – e.g., characters within a word (8 bits)
- Operations to pack /unpack bits into words
- Called *logical operations*

<table>
<thead>
<tr>
<th>Logical operations</th>
<th>C operators</th>
<th>Java operators</th>
<th>MIPS instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit-by-bit AND</td>
<td>&amp;</td>
<td>&amp;</td>
<td><em>and</em></td>
</tr>
<tr>
<td>Bit-by-bit OR</td>
<td></td>
<td></td>
<td><em>or</em></td>
</tr>
<tr>
<td>Bit-by-bit NOT</td>
<td>~</td>
<td>~</td>
<td><em>not</em></td>
</tr>
<tr>
<td>Shift left</td>
<td>&lt;&lt;</td>
<td>&lt;&lt;</td>
<td><em>sll</em></td>
</tr>
<tr>
<td>Shift right</td>
<td>&gt;&gt;</td>
<td>&gt;&gt;&gt;</td>
<td><em>srl</em></td>
</tr>
</tbody>
</table>
Logic Shifting

• Shift Left: `sll $s1,$s2,2 #s1=s2<<2`
  – Store in $s1$ the value from $s2$ shifted 2 bits to the left (they fall off end), inserting 0’s on right; $<<$ in C.
  
  Before: 0000 0002_{\text{hex}}
  0000 0000 0000 0000 0000 0000 0010_{\text{two}}
  
  After: 0000 0008_{\text{hex}}
  0000 0000 0000 0000 0000 0000 1000_{\text{two}}

  What arithmetic effect does shift left have?

• Shift Right: `srl` is opposite shift; $>>$
Arithmetic Shifting

• Shift right arithmetic moves \( n \) bits to the right (insert high order sign bit into empty bits)

• For example, if register \( $s0 \) contained
  
  \[
  1111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1110\ 0111\ 
  \]
  
  \( \text{two} = -25_{\text{ten}} \)

• If executed \text{sra} $s0, $s0, 4, result is:
  
  \[
  1111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1110\ 
  \]
  
  \( \text{two} = -2_{\text{ten}} \)

• Unfortunately, this is NOT same as dividing by \( 2^n \)
  
  – Fails for odd negative numbers
  
  – C arithmetic semantics is that division should round towards 0
Computer Decision Making

• Based on computation, do something different
• In programming languages: *if*-statement

• MIPS: *if*-statement instruction is

  \[ \text{beq register1, register2, L1} \]

  means: *go to statement labeled L1*
  if (value in register1) == (value in register2)
  ....otherwise, go to next statement

• \text{beq} stands for \textit{branch if equal}
• Other instruction: \text{bne} for \textit{branch if not equal}
Types of Branches

• **Branch** – change of control flow

• **Conditional Branch** – change control flow depending on outcome of comparison
  – branch *if* equal (\( \text{beq} \)) or branch *if not* equal (\( \text{bne} \))

• **Unconditional Branch** – always branch
  – a MIPS instruction for this: *jump* (\( j \))
Example *if* Statement

- Assuming translations below, compile *if* block
  
  \[ f \rightarrow \$s0 \quad g \rightarrow \$s1 \quad h \rightarrow \$s2 \]
  
  \[ i \rightarrow \$s3 \quad j \rightarrow \$s4 \]

  ```
  if (i == j)  
  bne \$s3,\$s4,Exit
  f = g + h;
  add \$s0,\$s1,\$s2
  
  Exit:
  ```

- May need to negate branch condition
Example *if-else* Statement

- Assuming translations below, compile

  \[ f \rightarrow s_0 \quad g \rightarrow s_1 \quad h \rightarrow s_2 \]
  \[ i \rightarrow s_3 \quad j \rightarrow s_4 \]

  if (i == j)
  \[ f = g + h; \]
  else
  \[ f = g - h; \]

  \[ \text{bne } s_3, s_4, \text{Else} \]
  \[ \text{add } s_0, s_1, s_2 \]
  \[ \text{j Exit} \]
  \[ \text{Else: sub } s_0, s_1, s_2 \]
  \[ \text{Exit:} \]
Administrivia

• Hopefully everyone turned-in HW0

• HW1 due 11:59:59pm Sunday 2/8
In the News
MIPS steers spacecraft to Pluto

• 4 MIPS R3000 32bit CPUs
  – Command and Data handling
  – Guidance and Control

• Launched 2006, first pics in July 2015

Inequalities in MIPS

• Until now, we’ve only tested equalities (== and != in C). General programs need to test < and > as well.

• Introduce MIPS Inequality Instruction: “Set on Less Than”

Syntax: \texttt{slt\ reg1,\ reg2,\ reg3}

Meaning:

\[
\begin{align*}
\text{if (reg2 < reg3)} & : \\
\quad \text{reg1} &= 1; \\
\text{else} & : \\
\quad \text{reg1} &= 0;
\end{align*}
\]

“set” means “change to 1”, “reset” means “change to 0”.
Inequalities in MIPS Cont.

• How do we use this? Compile by hand:
  \[
  \text{if } (g < h) \text{ goto Less; } \#g:$s0, h:$s1
  \]

• Answer: compiled MIPS code...
  \[
  \text{slt } \$t0,\$s0,\$s1 \# \$t0 = 1 \text{ if } g<h \\
  \text{bne } \$t0,\$zero,\text{Less} \# \text{ if } \$t0! = 0 \text{ goto Less}
  \]

• Register \$zero always contains the value 0, so \text{bne} and \text{beq}
  often use it for comparison after an \text{slt} instruction

• \text{sltu} treats registers as unsigned
Immediates in Inequalities

- **slti** an immediate version of **slt** to test against constants

```assembly
Loop: . . .

slti $t0,$s0,1  # $t0 = 1 if $s0<1
beq $t0,$zero,Loop  # goto Loop
               # if $t0==0
               # (if ($s0>=1))
```
Loops in C/Assembly

• Simple loop in C;  \( A[] \) is an array of ints
  
  \[
  \begin{align*}
  \text{do } & \quad \{ \quad g = g + A[i]; \\
  & \quad i = i + j; \\
  \text{ } & \quad \} \text{ while (} i \neq \text{ h) ;} \\
  \end{align*}
  \]

• Use this mapping:  \( g, \ h, \ i, \ j, \ \&A[0], \ $s1, \ $s2, \ $s3, \ $s4, \ $s5 \)

Loop:
\[
\begin{align*}
\text{\textcolor{red}{sll} } & \quad \textcolor{blue}{\$t1,\$s3,2} \quad \# \textcolor{blue}{\$t1=4*i} \\
\text{\textcolor{red}{addu} } & \quad \textcolor{blue}{\$t1,\$t1,\$s5} \quad \# \textcolor{blue}{\$t1=addr \ A+4i} \\
\text{\textcolor{red}{lw} } & \quad \textcolor{blue}{\$t1,0(\$t1)} \quad \# \textcolor{blue}{\$t1=A[i]} \\
\text{\textcolor{red}{add} } & \quad \textcolor{blue}{\$s1,\$s1,\$t1} \quad \# \textcolor{blue}{g=g+A[i]} \\
\text{\textcolor{red}{addu} } & \quad \textcolor{blue}{\$s3,\$s3,\$s4} \quad \# \textcolor{blue}{i=i+j} \\
\text{\textcolor{red}{bne} } & \quad \textcolor{blue}{\$s3,\$s2,\text{Loop}} \quad \# \textcolor{blue}{goto\ Loop} \\
\text{\textcolor{red}{bne} } & \quad \textcolor{blue}{\$s3,\$s2,\text{Loop}} \quad \# \textcolor{blue}{if\ i!=h}
\end{align*}
\]
And In Conclusion ...

• Computer words and vocabulary are called instructions and instruction set respectively
• MIPS is example RISC instruction set in this class
• Rigid format: 1 operation, 2 source operands, 1 destination
  – add, sub, mul, div, and, or, sll, srl, sra
  – lw, sw, lb, sb to move data to/from registers from/to memory
  – beq, bne, j, slt, slti for decision/flow control
• Simple mappings from arithmetic expressions, array access, if-then-else in C to MIPS instructions
