

## 61A Lecture 9

## Announcements

## Data Abstraction

### Data Abstraction

- Compound values combine other values together
  - A date: a year, a month, and a day
  - A geographic position: latitude and longitude
- Data abstraction lets us manipulate compound values as units
- Isolate two parts of any program that uses data:
  - How data are represented (as parts)
  - How data are manipulated (as units)
- Data abstraction: A methodology by which functions enforce an abstraction barrier between **representation** and **use**

All  
Programmers  
Great  
Programmers

## Rational Numbers

Exact representation of fractions  
A pair of integers  
As soon as division occurs, the exact representation may be lost! (Demo)  
Assume we can compose and decompose rational numbers:

Constructor  $\rightarrow$  `rational(n, d)` returns a rational number x  
Selectors

- `numer(x)` returns the numerator of x
- `denom(x)` returns the denominator of x

## Rational Number Arithmetic

$$\frac{3}{2} * \frac{3}{5} = \frac{9}{10}$$
$$\frac{nx}{dx} * \frac{ny}{dy} = \frac{nx*ny}{dx*dy}$$
$$\frac{3}{2} + \frac{3}{5} = \frac{21}{10}$$
$$\frac{nx}{dx} + \frac{ny}{dy} = \frac{nx*dy + ny*dx}{dx*dy}$$

Example

General Form

## Rational Number Arithmetic Implementation

```
def mul_rational(x, y):
    return rational(numer(x) * numer(y),
                    denom(x) * denom(y))
    Constructor
    Selectors
    
$$\frac{nx}{dx} * \frac{ny}{dy} = \frac{nx*ny}{dx*dy}$$

def add_rational(x, y):
    nx, dx = numer(x), denom(x)
    ny, dy = numer(y), denom(y)
    return rational(nx * dy + ny * dx, dx * dy)
    
$$\frac{nx}{dx} + \frac{ny}{dy} = \frac{nx*dy + ny*dx}{dx*dy}$$

def print_rational(x):
    print(numer(x), '/', denom(x))

def rationals_are_equal(x, y):
    return numer(x) * denom(y) == numer(y) * denom(x)

    • rational(n, d) returns a rational number x
    • numer(x) returns the numerator of x
    • denom(x) returns the denominator of x
    These functions implement an abstract representation for rational numbers
```

Pairs

### Representing Pairs Using Lists

```
>>> pair = [1, 2]          A list literal:  
>>> pair  
[1, 2]                   Comma-separated expressions in brackets  
  
>>> x, y = pair         "Unpacking" a list  
>>> x  
1  
>>> y  
2  
  
>>> pair[0]              Element selection using the selection operator  
1  
>>> pair[1]  
2  
  
>>> from operator import getitem   Element selection function  
>>> getitem(pair, 0)  
1  
>>> getitem(pair, 1)  
2
```

More lists next lecture

### Representing Rational Numbers

```
def rational(n, d):  
    """Construct a rational number that represents N/D.""""  
    return [n, d]
```

Construct a list

```
def numer(x):  
    """Return the numerator of rational number X.""""  
    return x[0]
```

Select item from a list

(Demo)

### Reducing to Lowest Terms

Example:

$$\frac{3}{2} * \frac{5}{3} = \frac{5}{2}$$

$$\frac{2}{5} + \frac{1}{10} = \frac{1}{2}$$

$$\frac{15}{6} * \frac{1/3}{1/3} = \frac{5}{2}$$

$$\frac{25}{50} * \frac{1/25}{1/25} = \frac{1}{2}$$

from fractions import gcd

```
def rational(n, d):  
    """Construct a rational that represents n/d in lowest terms.""""  
    g = gcd(n, d)  
    return [n//g, d//g]
```

(Demo)

### Abstraction Barriers

### Abstraction Barriers

Parts of the program that...	Treat rationals as...	Using...
Use rational numbers to perform computation	whole data values	add_rational, mul_rational, rationals_are_equal, print_rational
Create rationals or implement rational operations	numerators and denominators	rational, numer, denom
Implement selectors and constructor for rationals	two-element lists	list literals and element selection
Implementation of lists		

### Violating Abstraction Barriers

Does not use constructors

Twice!

```
add_rational([1, 2], [1, 4])
```

```
def divide_rational(x, y):  
    return [x[0] * y[1], x[1] * y[0]]
```

No selectors!

And no constructor!

### Data Representations

### What is Data?

- We need to guarantee that constructor and selector functions work together to specify the right behavior
- Behavior condition: If we construct rational number x from numerator n and denominator d, then numer(x)/denom(x) must equal n/d
- Data abstraction uses selectors and constructors to define behavior
- If behavior conditions are met, then the representation is valid

You can recognize an abstract data representation by its behavior

(Demo)

## Rationals Implemented as Functions

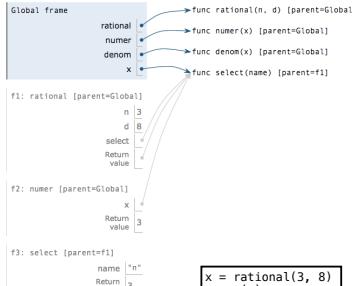

```
def rational(n, d):
    def select(name):
        if name == 'n':
            return n
        elif name == 'd':
            return d
    return select

def numer(x):
    return x('n')

def denom(x):
    return x('d')
```

Constructor is a higher-order function

Selector calls x
