Data Representations

Functions with Shared Local State

```python
def box(contents):
    def get():
        return contents
    def put(value):
        nonlocal contents
        contents = value
    return get, put

get, put = box('Hello')
before = get()
put('Goodbye')
after = get()
```

```
Global frame                              func box(contents) [parent=Global]

                      box                 func get() [parent=f1]

f1: box [parent=Global]                   func put(value) [parent=f1]

         contents  "Hello"
              get
              put
```

Interactive Diagram
Pairs Implemented as Functions

```
def pair(x, y):
    def dispatch(m):
        if m == 'first':
            return x
        elif m == 'second':
            return y
    return dispatch
```

This function represents the pair (x, y)

Constructor is a higher-order function

```
>>> p = pair(3, pair(4, 5))
>>> p('first')
3
>>> p('second')('first')
4
>>> p('second')('second')
5
```

(Demo)

Linked Lists (Sneak Preview)

- An empty list is called "nil" and represented as None

- A non-empty list is represented as a pair
  - The first element of the pair is the first element of the list
  - The second element of the pair is the rest of the list

```
nil = None
def list_len(s):
    if s is nil:
        return 0
    else:
        return 1 + list_len(s('second'))
```

```
def append(s, x):
    if s is nil:
        return pair(x, nil)
    else:
        first, rest = s('first'), s('second')
        return pair(first, append(rest, x))
```

(Demo)

An Inefficient Dictionary Implementation

• A list of key-value pairs can be used to implement dictionary behavior

```
>>> d = dict_dispatch()
>>> d('set')('I', 1)
>>> d('set')('V', 5)
>>> d('set')('X', 10)
```

(Demo)

Dispatch Dictionaries

Dispatch Dictionaries

Enumerating different messages in a conditional statement isn't very convenient:
- Equality tests are repetitive
- We can't add new messages without re-writing the dispatch function

A dispatch dictionary has messages as keys and functions (or data objects) as values

Dictionaries handle the message look-up logic; we can concentrate on implementing behavior

```python
def box_dispatch(contents):
    def dispatch(m):
        if m == 'contents':
            return contents
        if m == 'put':
            def put(value):
                nonlocal contents
                contents = value
            return put
    return dispatch
```

```python
def box_dict(contents):
    def put(value):
        d['contents'] = value
    d = {'contents': contents, 'put': put}
    return d
```

(Demo)

Constraint Networks

Solving for Variables in an Equation

a + b = c

a = c − b

b = c − a

Boltzmann's constant

p ∗ v = n ∗ k ∗ t

9 ∗ c = 5 ∗ (f − 32)

Algebraic equations are *declarative:* They describe a relation among different quantities

ONE WAY Python functions are *procedural:* They describe how to compute a result from a set of input arguments
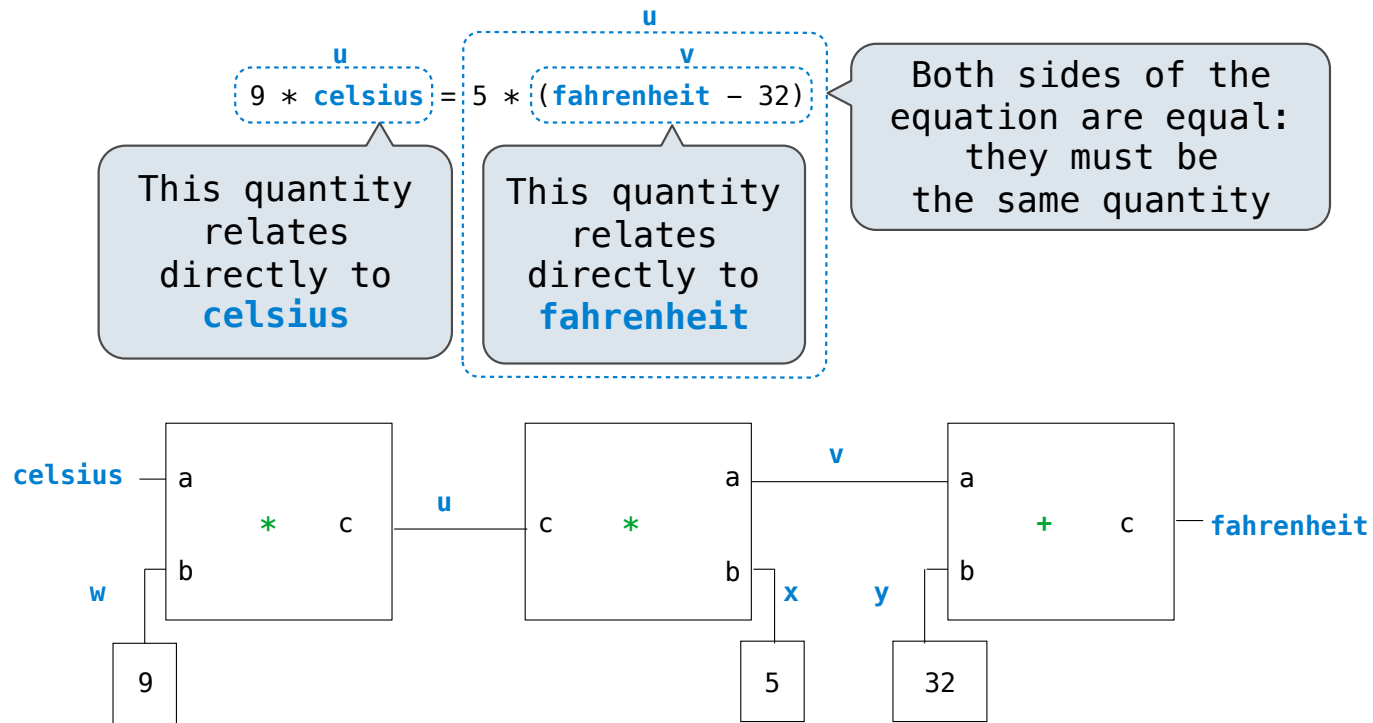

Constraint programming:
- We define the relationship between quantities
- We provide values for the "known" quantities
- The system computes values for the "unknown" quantities

Challenge: We want a general means of combination.

Combination idea: All intermediate quantities have values too.
