

1 Inheritance Practice

```

public class Q {
    public void a() {
        System.out.println("Q.a");
    }
    public void b() {
        a();
    }
    public void c() {
        e();
    }
    public void d() {
        e();
    }
    public static void e() {
        System.out.println("Q.e");
    }
}

public class R extends Q {
    public void a() {
        System.out.println("R.a");
    }
    public void d() {
        e();
    }
    public static void e() {
        System.out.println("R.e");
    }
}

public class S {
    public static void main(String[]
        args) {
        R aR = new R();
        run(aR);
    }
    public static void run(Q x) {
        x.a();          /* Output: R.a */
        x.b();          /* Output: R.a */
        x.c();          /* Output: Q.e */
        ((R)x).c();    /* Output: Q.e */
        x.d();          /* Output: R.e */
        ((R)x).d();    /* Output: R.e */
    }
}

```

In run, write what gets printed next to each line.

x.a() will call the *a()* according to the variable's dynamic type.

x.b(), because *b()* is not overridden, will use the *b()* in *Q*. Then, *b()* selects which *a()* to run based on the variable's dynamic type.

x.c() runs *Q.c()*, which runs *Q.e()*. Note that *e()* is a static method, so it uses the static type to look up which function to call.

((R)x).c() makes the same series of calls. Again, *e()* is a static method, so it uses the static type to look up which function to call.

x.d() runs *R.d()*, which runs *this.e()*, this has a static type of *R* in *R.d()* so *R.e()* is run.

((R)x).d() makes the same series of calls.

2 Reduce

We'd like to write a method `reduce`, which uses a `BinaryFunction` interface to accumulate the values of a `List` of integers into a single value. `BinaryFunction` can operate (through the `apply` method) on two integer arguments and return a single integer. Note that `reduce` can now work with a range of binary functions (for example, addition and multiplication). Write two classes `Adder` and `Multiplier` that implement `BinaryFunction`. Then, fill in `reduce` and `main`, and define types for `add` and `mult` in the space provided.

```
import java.util.ArrayList;
import java.util.List;
public class ListUtils {
    /** If the list is empty, return 0.
     * If it has one element, return that element.
     * Otherwise, apply a function of two arguments cumulatively to the
     * elements of list and return a single accumulated value.
     * Does not modify the list. */
    public static int reduce(BinaryFunction func, List<Integer> list) {
        if (list.size() == 0) { return 0; }
        int soFar = list.get(0);
        for (int i = 1; i < list.size(); i++) {
            soFar = func.apply(soFar, list.get(i));
        }
        return soFar;
    }
    public static void main(String[] args) {
        ArrayList<Integer> integers = new ArrayList<>();
        integers.add(2); integers.add(3); integers.add(4);
        Adder add = new Adder();
        Multiplier mult = new Multiplier();
        reduce(add, integers); //Should evaluate to 9
        reduce(mult, integers); //Should evaluate to 24
    }
}

interface BinaryFunction {
    int apply(int x, int y);
}

public class Adder implements BinaryFunction {
    public int apply(int x, int y) {
        return x + y;
    }
}

public class Multiplier implements BinaryFunction {
    public int apply(int x, int y) {
        return x * y;
    }
}
```

We declare an interface `BinaryFunction` which our `Adder` and `Multiplier` classes can implement. Writing a common interface is important, because it allows us to write a `reduce` function that is capable of accepting many kinds of functions. Note that interface methods are public by default, so `apply` must be public in `Adder` and `Multiplier`.

3 Even Odd

Implement the method `evenOdd` by *destructively* changing the ordering of a given `IntList` so that even indexed links precede odd indexed links. For instance, if `lst` is defined as `IntList.list(0, 3, 1, 4, 2, 5)`, `evenOdd(lst)` would modify `lst` to be `IntList.list(0, 1, 2, 3, 4, 5)`. You may not need all the lines.

Hint: Make sure your solution works for lists of odd and even lengths.

```
public class IntList {
    public int first;
    public IntList rest;
    public IntList (int f, IntList r) {
        this.first = f;
        this.rest = r;
    }
    public static void evenOdd(IntList lst) {
        if (lst == null || lst.rest == null) {
            return;
        }
        IntList oddList = lst.rest;
        IntList second = lst.rest;
        while (lst.rest != null && oddList.rest != null) {
            lst.rest = lst.rest.rest;
            oddList.rest = oddList.rest.rest;
            lst = lst.rest;
            oddList = oddList.rest;
        }
        lst.rest = second;
    }
}
```

Here is an alternate solution.

```
public class IntList {
    public int first;
    public IntList rest;
    public IntList (int f, IntList r) {
        this.first = f;
        this.rest = r;
    }
    public static void evenOdd(IntList lst) {
        if (lst == null || lst.rest == null || lst.rest.rest == null) {
            return;
        }
        IntList second = lst.rest;
        int index = 0;
        while (!(index % 2 == 0 && (lst.rest == null || lst.rest.rest == null))) {
            IntList temp = lst.rest;
            lst.rest = lst.rest.rest;
            lst = temp;
            index++;
        }
        lst.rest = second;
    }
}
```

```
}  
}
```

For any linked list, observe that we simply want to change the `rest` attribute of each `IntList` instance to skip an `IntList` instance. Looking at `lst`, we want to link 0 to 1, 3 to 4, and so on. This will constitute the work of the body of the `while` loop, so we just need to figure out how to link the last even indexed `IntList` instance to the first odd indexed `IntList` instance. To keep track of the first odd indexed `IntList` instance, we can use `second`. Now, we just need to exit the `while` loop when we are at the last even indexed `IntList` instance. This occurs when the index is even and we are either at the second to last element (`lst.rest.rest == null`) or the last element (`lst.rest == null`).

4 Inheritance Infiltration

Access modifiers are critical when it comes to security. Look at the PasswordChecker and User classes below.

```
public class PasswordChecker {
    /** Returns true if the provided login and password are correct. */
    public boolean authenticate(String login, String password) {
        // Does some secret authentication stuff...
    }
}

public class User {
    private String username;
    private String password;

    public void login>PasswordChecker p) {
        p.authenticate(username, password);
    }
}
```

Even though the username and password variables are private, the login and authenticate methods are both public. We can use inheritance to take advantage of this and extract the password of any given User object. Complete the PasswordExtractor class below so that calling extractPassword returns the password of a given User. You may not modify the provided classes (i.e. you may not change the implementations of PasswordChecker or User).

```
public class PasswordExtractor extends PasswordChecker {
    String extractedPassword;

    public String extractPassword(User u) {
        u.login(this);
        return extractedPassword;
    }

    @Override
    public boolean authenticate(String login, String password) {
        extractedPassword = password; // Victory is mine >:)
        return true; // or false. Needs to return something to compile.
    }
}
```

Hint: The login method of User passes in the username and password fields as parameters to the authenticate method of a given PasswordChecker. Think about how we can take advantage of method overriding to gain access to the password.

By letting us subclass PasswordChecker, we can overwrite the authenticate method to capture the password in a local variable. By calling a user's login method and passing ourselves in, we can force the user to provide its password. Finally, we can return the extracted password. We could fix this security hole by making PasswordChecker no longer a public class.
