# Network Layer Enhancements

EECS 122: Lecture 14

---

Department of Electrical Engineering and Computer Sciences  
University of California  
Berkeley

---

## Today

- We have studied the network layer mechanisms that enable “best effort service”
- Today’s focus: How to make best effort better!
  - How are virtual circuits established?
    - Why do they help in improving performance?
  - What does it mean to treat the packets of a network “fairly”
    - Max Min Fairness
  - What network layer mechanisms improve performance?
    - Scheduling
    - Policing

## Network Service Models

**Q:** What *service model* for "channel" transporting datagrams from sender to rcvr?

Example services for individual datagrams:

- Guaranteed delivery
- Guaranteed delivery with less than 40 msec delay

Example services for a flow of datagrams:

- In-order datagram delivery
- Guaranteed minimum bandwidth to flow
- Jitter Control: Restrictions on changes in inter-packet spacing

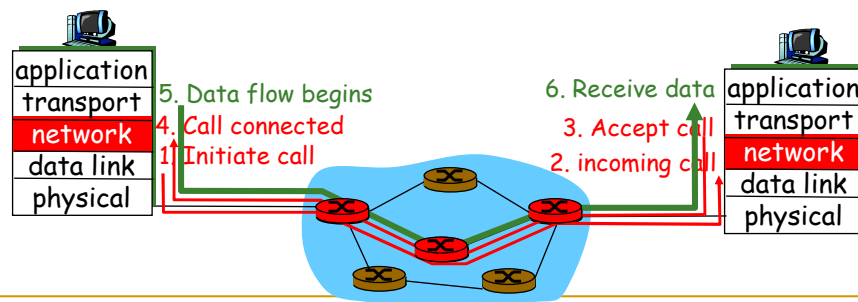

**Need Virtual Circuits to Provide Flow-Based Services**

## Network layer service models:

Network Architecture	Service Model	Guarantees ?				Congestion feedback
		Bandwidth	Loss	Order	Timing	
Internet	best effort	none	no	no	no	no (inferred via loss)
ATM	CBR	constant rate	yes	yes	yes	no congestion
ATM	VBR	guaranteed rate	yes	yes	yes	no congestion
ATM	ABR	guaranteed minimum	no	yes	no	yes
ATM	UBR	none	no	yes	no	no

## Virtual circuits: signaling protocols

- used to setup, maintain teardown VC
- used in ATM, frame-relay, X.25
- not used in today's Internet

March 2, 2006

EECS122 Lecture 14 (AKP)

5

## Virtual circuits

- Signaling: call setup, teardown for each call *before* data can flow
- Addressing: each packet carries VC identifier (not destination host address)
- Router State: every router on source-dest path maintains "state" for each passing connection
- Resource Allocation: link, router resources (bandwidth, buffers) may be *allocated* to VC

March 2, 2006

EECS122 Lecture 14 (AKP)

6

## VC implementation

A VC consists of:

1. Path from source to destination
  2. VC numbers, one number for each link along path
  3. Entries in forwarding tables in routers along path
- Packet belonging to VC carries a VC number.
  - VC number must be changed on each link.
    - New VC number comes from forwarding table
    - This is label switching!

March 2, 2006

EECS122 Lecture 14 (AKP)

7

## Forwarding table

Forwarding table in northwest router:

Incoming interface	Incoming VC #	Outgoing interface	Outgoing VC #
1	12	3	22
2	63	1	18
3	7	2	17
1	97	3	87
...	...	...	...

**Routers maintain connection state information**

March 2, 2006

EECS122 Lecture 14 (AKP)

8

## Allocating Resources

- Circuit switched networks allocate resources by allocating timeslots during which no other flow can use the link
- Virtual Circuit networks use
  - Scheduling
  - Policing
  - Drop Policies
  - Call Admission
- What are these things?
  - Let's look at a simple motivating example

March 2, 2006

EECS122 Lecture 14 (AKP)

9

## Example

- 0.5Mbps IP phone, FTP share 1.5 Mbps link.
  - bursts of FTP can congest router, cause audio loss
  - This is because the link at R1 is using First Come First Serve

### Classification and Scheduling

packet marking needed for router to distinguish between different classes; and new router policy to treat packets accordingly

March 2, 2006

EECS122 Lecture 14 (AKP)

10

## Example

- what if applications misbehave (audio sends higher than declared rate)
  - policing: force source adherence to bandwidth allocations
- marking and policing at network edge:

**Policing**  
provide protection (*isolation*) for one class from others

March 2, 2006

EECS122 Lecture 14 (AKP)

11

## Example

- Allocating *fixed* (non-sharable) bandwidth to flow: *inefficient* use of bandwidth if flows doesn't use its allocation

**Efficiency**

While providing isolation, it is desirable to use resources as efficiently as possible

March 2, 2006

EECS122 Lecture 14 (AKP)

12

## Example

- *Basic fact of life:* can not support traffic demands beyond link capacity

### Call Admission

flow declares its needs, network may block call (e.g., busy signal) if it cannot meet needs

## Mechanisms to Improve Best Effort

- Classification and Scheduling
- Drop Policies
- Policing
- Call admission
- Implementing even a subset of these can help!
- Next Question....
  - How should we use these mechanisms to improve performance?

## Fairness

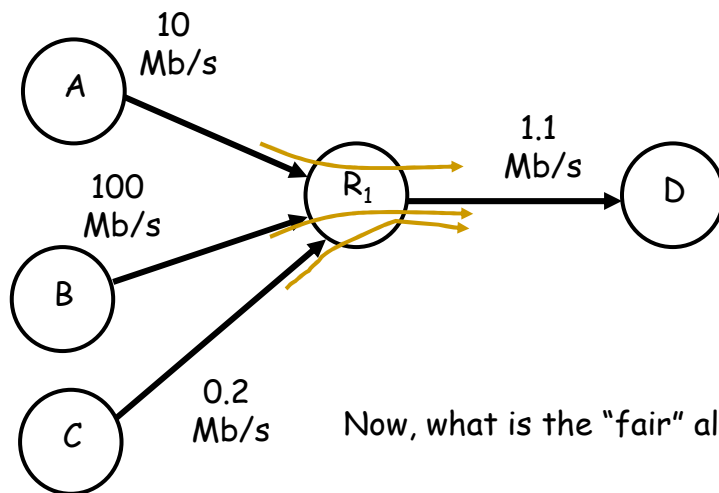

What is the "fair" allocation:  
(0.55Mb/s, 0.55Mb/s) or (0.1Mb/s, 1Mb/s)?

March 2, 2006

EECS122 Lecture 14 (AKP)

15

## Fairness

Now, what is the "fair" allocation?

March 2, 2006

EECS122 Lecture 14 (AKP)

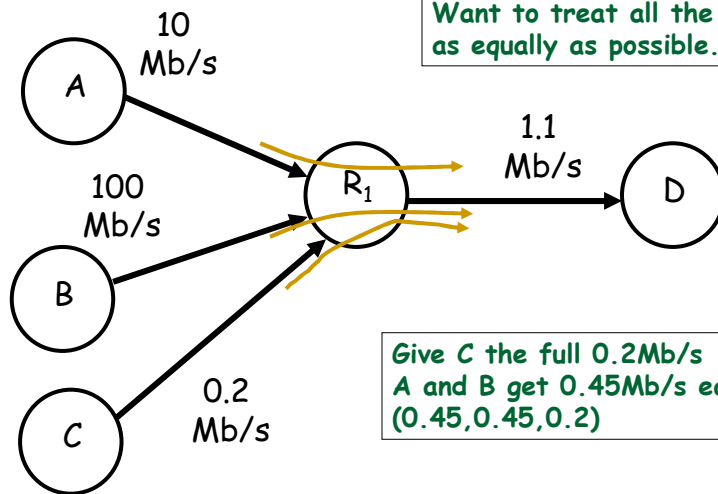

16

## Fairness

### Max-Min Fair Allocation

Want to treat all the flows as equally as possible.

Give C the full 0.2 Mb/s  
A and B get 0.45 Mb/s each  
(0.45, 0.45, 0.2)

March 2, 2006

EECS122 Lecture 14 (AKP)

17

## Another Example

Allocate 0.1 to C. This leaves 0.9 for the rest.  
Each of A, B and D are  $> 0.3$  so allocate them each 0.3  
Max-Min Fair Allocation is  $(.3, .3, .1, .3)$

March 2, 2006

EECS122 Lecture 14 (AKP)

18

## Max-Min Fairness Algorithm

$N$  flows share a link of rate  $C$ . Flow  $f$  wishes to send at rate  $W(f)$ , and is allocated rate  $R(f)$ .

1. Pick the flow,  $f$ , with the smallest desired rate.
2. If  $W(f) < C/N$ , then set  $R(f) = W(f)$ .
3. If  $W(f) > C/N$ , then set  $R(f) = C/N$ .
4. Set  $N = N - 1$ .  $C = C - R(f)$ .
5. If  $N > 0$  goto 1.

## Example Revisited

- Round 1: Set  $R(f_C) = 0.1$   
Round 2: Set  $R(f_B) = 0.9/3 = 0.3$   
Round 3: Set  $R(f_D) = 0.6/2 = 0.3$   
Round 4: Set  $R(f_A) = 0.3/1 = 0.3$

Router  
Without any  
classification

queue

Classification  
and  
Scheduling

Router  
With M classes

Model of router queues

Nick Mckeown

## Scheduling Goals

- Flexibility
  - Must be able to accommodate a wide range of performance objectives
  - Must be “fair”
- Predictable/Analyzable
  - Must have some way to determine if the performance objectives are met
- Implementable
  - Cost
  - Performance

# Priority Scheduling

Transmit highest priority queued packet

- multiple *classes*, with different priorities
  - class may depend on marking or other header info, e.g. IP source/dest, port numbers, etc..
  - Problem: Higher priorities can hog

March 2, 2006

EECS122 Lecture 14 (AKP)

23

# Round Robin

- multiple classes
- cyclically scan class queues, serving one from each class (if available)
- Problems:
  - What if the flows require different rates?
  - What if the packet sizes are not equal?

March 2, 2006

EECS122 Lecture 14 (AKP)

24

## Fair Queueing

- This treats all the flows equally but allows for unequal packet sizes
- 1. Flows are scheduled one bit at a time, in a round-robin fashion.
- 2. This is called Bit-by-Bit Fair Queueing or Processor Sharing

March 2, 2006

EECS122 Lecture 14 (AKP)

25

## Weighted Bit-by-Bit Fair Queueing

Likewise, flows can be allocated different rates by servicing a different number of bits for each flow during each round.

Also called "Generalized Processor Sharing (GPS)"

March 2, 2006

EECS122 Lecture 14 (AKP)

26

# Packetized Weighted Fair Queueing (WFQ)

**Problem:** We need to serve a whole packet at a time.

**Solution:**

1. Determine what time a packet,  $p$ , would complete if we served flows bit-by-bit. Call this the packet's finishing time,  $F_p$ .
2. Serve packets in the order of increasing finishing time.

**Theorem:** Packet  $p$  will depart before  $F_p + (\text{max packet transmission delay})$

Also called "Packetized Generalized Processor Sharing (PGPS)"

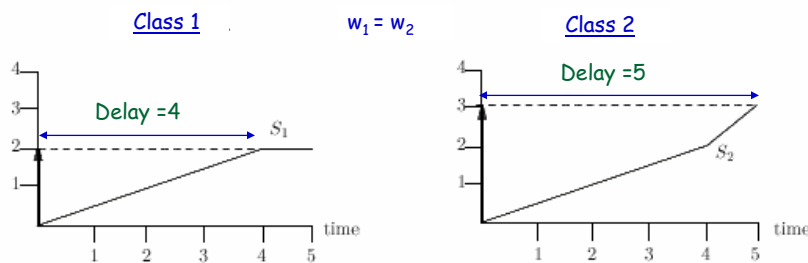

March 2, 2006

EECS122 Lecture 14 (AKP)

27

# Generalized Processor sharing can be used to control the delay at a router

- Example: Two Flows share a link of 1Mbs
  - Both flows have large chunks to send
  - Case 1: Treat them equally

March 2, 2006

EECS122 Lecture 14 (AKP)

28

## Adjust weights to change delay

- Suppose we want to reduce flow 2's delay to 4

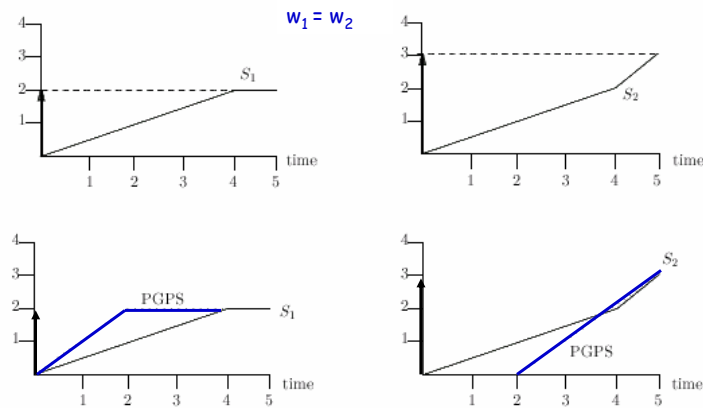

March 2, 2006

EECS122 Lecture 14 (AKP)

29

## Let's look at the what happens when serve packets not bits

In this example, no packets finish later under WFQ

March 2, 2006

EECS122 Lecture 14 (AKP)

30

## WFQ Example II

$$w_1 = w_2$$

- Packets out of order
  - Packet from Flow 1 finishes late under WFQ
  - Theorem: Maximum lateness is  $L_{\max}/C$  where  $L_{\max}$  is the maximum packet size allowed. WFQ never falls further behind.

March 2, 2006

EECS122 Lecture 14 (AKP)

31

## The use of WFQ for (weighted) fairness

- WFQ can be used to provide different rates to different flows.
- Most routers today implement WFQ and can be used to give different rates to different flows. (Not used much yet).
- Different definitions of a flow are possible:  
Application flow, all packets to a destination, all packets from a source, all http packets, the CEO's traffic, ... etc.

March 2, 2006

EECS122 Lecture 14 (AKP)

32

## Policing Mechanisms

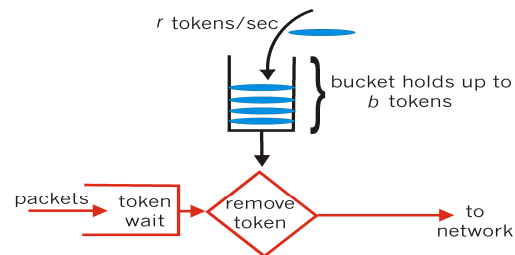

**Goal:** limit traffic to not exceed declared parameters

Three common-used criteria:

- **(Long term) Average Rate:** how many pkts can be sent per unit time (in the long run)
  - crucial question: what is the interval length: 100 packets per sec or 6000 packets per min have same average!
- **Peak Rate:** e.g., 6000 pkts per min. (ppm) avg.; 1500 ppm peak rate
- **(Max.) Burst Size:** max. number of pkts sent consecutively (with no intervening idle)

## Policing Mechanisms

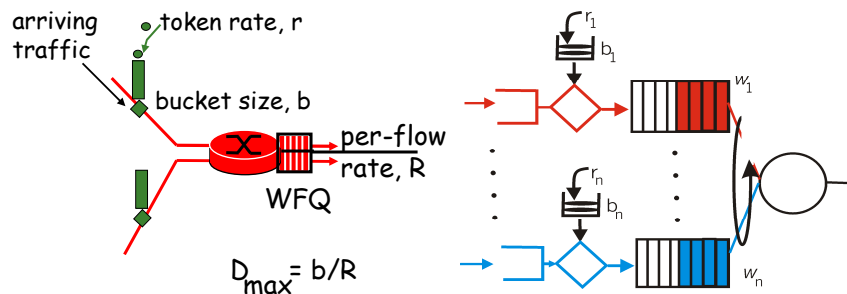

**Token Bucket:** limit input to specified Burst Size and Average Rate.

- bucket can hold  $b$  tokens
- tokens generated at rate  $r$  token/sec unless bucket full
- *over interval of length  $t$ : number of packets admitted less than or equal to  $(r t + b)$ .*

## Policing Mechanisms (more)

- token bucket, WFQ combine to provide guaranteed upper bound on delay, i.e., *QoS guarantee!*

March 2, 2006

EECS122 Lecture 14 (AKP)

35

## Summary

- Best Effort can be improved significantly through the addition of network layer flows
- Virtual circuits implement flows
- Even in the absence of flows, router mechanisms such as scheduling and intelligent drop policies can improve performance significantly
- Next time: Quality of Service in the internet
