

Transport Layer

EECS 122
Feb. 7, 2006

Slides adapted from Kurose and Ross.

Transport Layer 1

Transport services and protocols

- provide *logical communication* between app processes running on different hosts
- transport protocols run in end systems
 - send side: breaks app messages into **segments**, passes to network layer
 - rcv side: reassembles segments into messages, passes to app layer
- more than one transport protocol available to apps
 - Internet: TCP and UDP

Transport Layer 4

Administrivia

- HW 1 due in class; solns out this afternoon
- HW 2 out later today

Transport Layer 2

Transport vs. network layer

- *network layer*: logical communication between hosts
- *transport layer*: logical communication between processes
 - relies on, enhances, network layer services

Processes can be different applications (HTTP, DNS, etc) running on the same host and they are multiplexed together.

Transport Layer 5

Transport Layer

Our goals:

- understand principles behind transport layer services:
 - reliable data transfer
 - flow control
 - congestion control
- learn about transport layer protocols in the Internet:
 - UDP: connectionless transport
 - TCP: connection-oriented transport

Transport Layer 3

Multiplexing/demultiplexing

Demultiplexing at rcv host:
delivering received segments to correct socket

Multiplexing at send host:
gathering data from multiple sockets, enveloping data with header (later used for demultiplexing)

■ = socket ○ = process

Transport Layer 6

Internet transport-layer protocols

- reliable, in-order delivery (TCP)
 - reliable data service
 - congestion control
 - flow control
 - connection setup
- unreliable, unordered delivery: UDP
 - no-frills extension of "best-effort" IP
- services not available:
 - delay guarantees
 - bandwidth guarantees

UDP checksum

Goal: detect "errors" (e.g., flipped bits) in transmitted segment

Sender:

- treat segment contents as sequence of 16-bit integers
- checksum: addition (1's complement sum) of segment contents
- sender puts checksum value into UDP checksum field

Receiver:

- compute checksum of received segment
- check if computed checksum equals checksum field value:
 - NO - error detected
 - YES - no error detected. *But maybe errors nonetheless? More later*

UDP: User Datagram Protocol [RFC 768]

- "no frills," "bare bones" Internet transport protocol
- "best effort" service, UDP segments may be:
 - lost
 - delivered out of order to app
- **connectionless:**
 - no handshaking between UDP sender, receiver
 - each UDP segment handled independently of others

Why is there a UDP?

- no connection establishment (which can add delay)
- simple: no connection state at sender, receiver
- small segment header
- no congestion control: UDP can blast away as fast as desired

Internet Checksum Example

Note

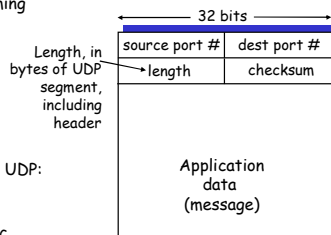

- When adding numbers, a carryout from the most significant bit needs to be added to the result

- Example: add two 16-bit integers

	1 1 1 0 0 1 1 0 0 1 1 0 0 1 1 0
	1 1 0 1 0 1 0 1 0 1 0 1 0 1 0 1
wraparound	① 1 0 1 1 1 0 1 1 1 0 1 1 1 0 1 1
sum	1 0 1 1 1 0 1 1 1 0 1 1 1 1 0 0
checksum	0 1 0 0 0 1 0 0 0 1 0 0 0 0 1 1

UDP: more

- often used for streaming multimedia apps
 - loss tolerant
 - rate sensitive
- other UDP uses
 - DNS
 - SNMP
- reliable transfer over UDP: add reliability at application layer
 - application-specific error recovery!

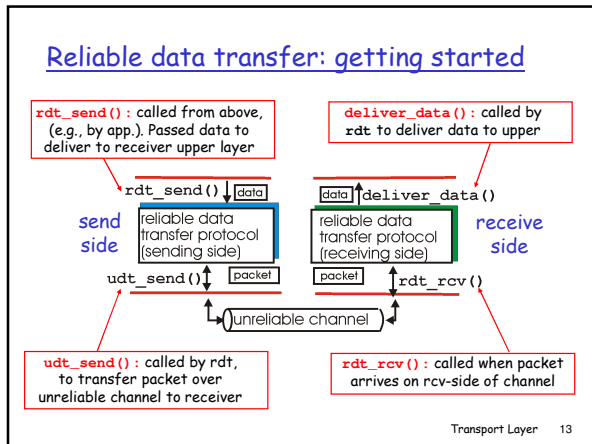

UDP segment format

Principles of Reliable data transfer

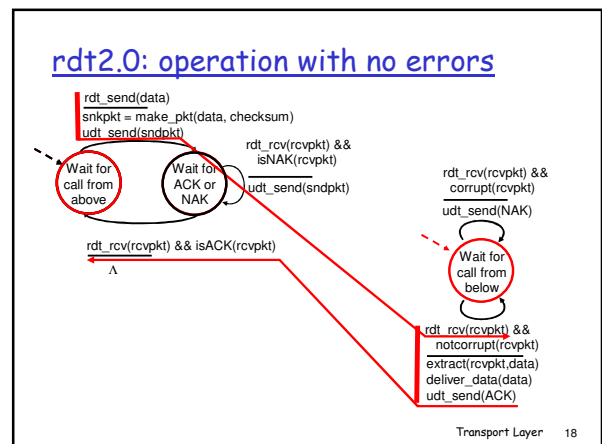

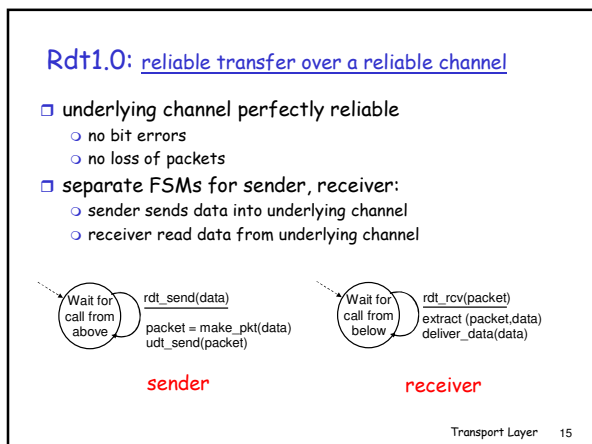

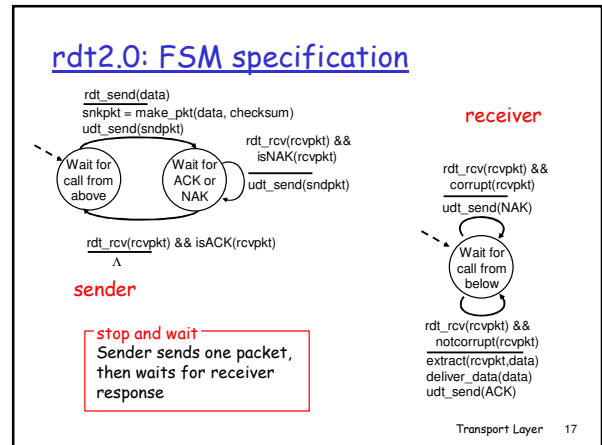

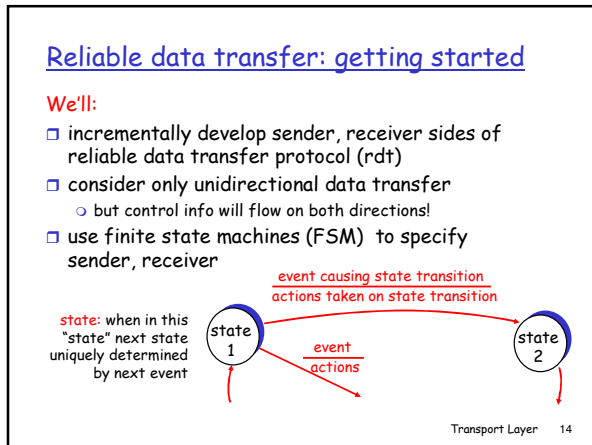

- important in app., transport, link layers

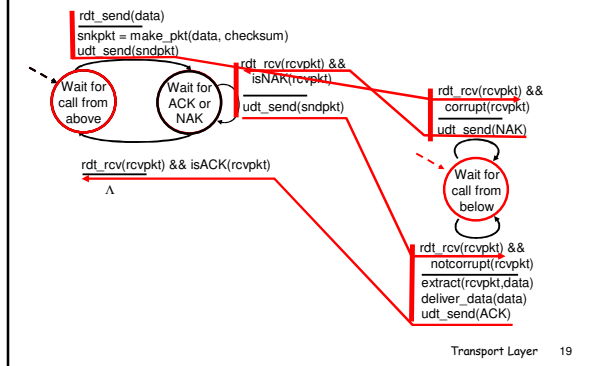

- characteristics of unreliable channel will determine complexity of reliable data transfer protocol (rdt)

- ### Rdt2.0: channel with bit errors
- underlying channel may flip bits in packet
 - checksum to detect bit errors
 - the question: how to recover from errors:
 - acknowledgements (ACKs): receiver explicitly tells sender that pkt received OK
 - negative acknowledgements (NAKs): receiver explicitly tells sender that pkt had errors
 - sender retransmits pkt on receipt of NAK
 - new mechanisms in rdt2.0 (beyond rdt1.0):
 - error detection
 - receiver feedback: control msgs (ACK,NAK) rcvr->sender
- Transport Layer 16

rdt2.0: error scenario

rdt2.0 has a fatal flaw!

What happens if

- ACK/NAK corrupted?**
- sender doesn't know what happened at receiver!
 - can't just retransmit: possible duplicate

Handling duplicates:

- sender retransmits current pkt if ACK/NAK garbled
- sender adds *sequence number* to each pkt
- receiver discards (doesn't deliver up) duplicate pkt
