---

---

---

---

## Review

- DH key exchange protocol
- Password authentication protocol
- Random number generation

2

---

---

---

---

---

---

---

---

## Lessons Learned

- Seeds must be unpredictable
- Algorithm for generating pseudorandom bits must be secure

3

---

---

---

---

---

---

---

---

## Generating Pseudorandom Numbers

- **True random number generator (TRNG)**
  - Generates bits that are distributed uniformly at random, so that all outputs are equally likely, with no patterns, correlations, etc.
- **Cryptographically secure pseudorandom number generator (CS-PRNG)**
  - Taking a short true-random seed, and generates long sequence of bits that is computationally indistinguishable from true random bits

4

---

---

---

---

---

---

---

---

## CS-PRNG

- **CS-PRNG: cryptographically secure pseudorandom number generator**
  - G: maps a seed to an output  $G(S)$ 
    - » E.g.,  $G: \{0,1\}^{128} \rightarrow \{0,1\}^{1000000}$
  - Let  $K$  denote a random variable distributed uniformly at random in domain of  $G$
  - Let  $U$  denote a random variable distributed uniformly at random in range of  $G$
  - $G$  is secure if output  $G(K)$  is computationally indistinguishable from  $U$
- **Sample construction**
  - Use the seed as a key  $k$ , and compute  $\text{AES-CBC}(k, 0^n)$

5

---

---

---

---

---

---

---

---

## TRNG (I)

- **TRNG should be random and unpredictable**
- **Good or bad choices?**
  - IP addresses
  - Contents of network packets
  - Process IDs
  - High-speed clock
  - Soundcard
  - Keyboard input
  - Disk timings

6

---

---

---

---

---

---

---

---

## TRNG (II)

- How to convert non-uniform sources of randomness into TRNG?
  - Use a cryptographic hash function, such as SHA1
  - Suppose  $x$  is a value from an imperfect source, or a concatenation of values from multiple sources, and it is impossible for an attacker to predict the exact value  $x$  except with probability  $1/2^n$
  - Then  $\text{hash}(x)$  truncated to  $n$  bits should provide a  $n$ -bit value that is uniformly distributed, if  $\text{hash}()$  is secure

7

---

---

---

---

---

---

---

---

## Secret Sharing

- A trusted authority TA has a secret  $K$
- Wants to split  $K$  into  $n$  shares  $S_1, \dots, S_n$ , distributing to  $n$  users  $U_1, \dots, U_n$  respectively, s.t.
  - A reconstruction algorithm can be used to efficiently reconstruct  $K$  from any  $t$  of the  $n$  shares
  - Any  $t-1$  of the  $n$  shares reveal no information about  $K$
- Such a scheme is called an  $(n,t)$  threshold secret sharing scheme

8

---

---

---

---

---

---

---

---

## $(n,n)$ Secret Sharing Scheme

- Suppose the secret  $K$  is an integer btw  $0$  and  $M-1$
- $(n,n)$  threshold scheme:
  - Pick  $S_1, \dots, S_{n-1}$  uniformly at random btw  $0$  and  $M-1$
  - Set  $S_n = K - (S_1 + \dots + S_{n-1}) \bmod M$
- How to reconstruct  $K$ ?
- What happens if  $n-1$  users get together?

9

---

---

---

---

---

---

---

---

## (n,t) Threshold Scheme

- **Polynomials modulo prime p**
  - Polynomials whose coefficients are elements mod p
  - E.g.,  $f(x) = x^2 + 2x + 4 \pmod{5}$
  - Degree-n polynomial  $f \pmod{p}$  is uniquely determined by any  $n+1$  distinct pairs  $(x_i, y_i)$  s.t.  $f(x_i) = y_i$ 
    - » Lagrange interpolation
- **To (n,t) threshold share secret K:**
  - Pick a random polynomial  $f \pmod{p}$  of degree  $t-1$  s.t.  $f(0) = K$
  - Share  $s_i = f(i)$  for  $i = 1$  to  $n$
  - How to recover K?
  - How many shares do you need to recover K?
  - What happens if you have fewer shares than  $t$ ?

10

---

---

---

---

---

---

---

---

## Administravia

- Hw1 hand-in procedure

11

---

---

---

---

---

---

---

---

## Zero-knowledge Proof

- Alice->Bob: I know the solution to Que 3 in hw 1, but I can't tell you what the solution is
- Bob->Alice: tell me, o.w. I don't believe you
- Alice->Bob: Ok, I'll prove to you that I know the solution in **Zero-knowledge**

12

---

---

---

---

---

---

---

---

## Zero-knowledge protocol

- Idea: (interactive) proof btw prover A & verifier B
- At the end of the proof, B is convinced A knows a secret satisfying a fact F
- But B has no information about that secret

13

---

---

---

---

---

---

---

---

## The Zero-knowledge Cave (I)

- Alice wants to prove to Bob that she knows how the magic word to open door
  - Without telling Bob the magic word

14

---

---

---

---

---

---

---

---

## The Zero-knowledge Cave (II)

1. Alice walks to either C or D;
2. Bob stands at V, calling either Left or Right;
3. Alice complies, using her magic word to open door if needed;
4. Alice & Bob repeats steps 1-3 for n times

15

---

---

---

---

---

---

---

---

### The Zero-knowledge Cave (III)

- What if Alice didn't know the magic word?
- What does Bob learn at the end of the proof?

16

---

---

---

---

---

---

---

---

### How to prove knowledge of square root

- Finding square root mod  $N=pq$  is as hard as factoring
- A knows  $b$  s.t.  $b^2 \equiv y \pmod{pq}$ , & wishes to prove to B that she knows such  $b$ .
- A  $\rightarrow$  B:  $s = r^2 \pmod{pq}$  (A picks random  $r$ )
- B flips coin
- B  $\rightarrow$  A: coin flip
- If heads
  - A  $\rightarrow$  B:  $t = r \pmod{pq}$
  - B verifies  $t^2 \equiv s \pmod{pq}$
- If tails
  - A  $\rightarrow$  B:  $t = rb \pmod{pq}$
  - A verifies  $t^2 \equiv sy \pmod{pq}$
- What if A didn't know the square root?
- What did B learn after the proof?
