

Proj 2 announcements

Digital certificates

CA verifies Google representative
that they are indeed from
own google.com

certificate for Google =

sign

SK_{CA}

(google.com has PK_G)
expiry

↓
certificate authority

Advantages:

→ can obtain certificate from anyone, don't need
online service

→

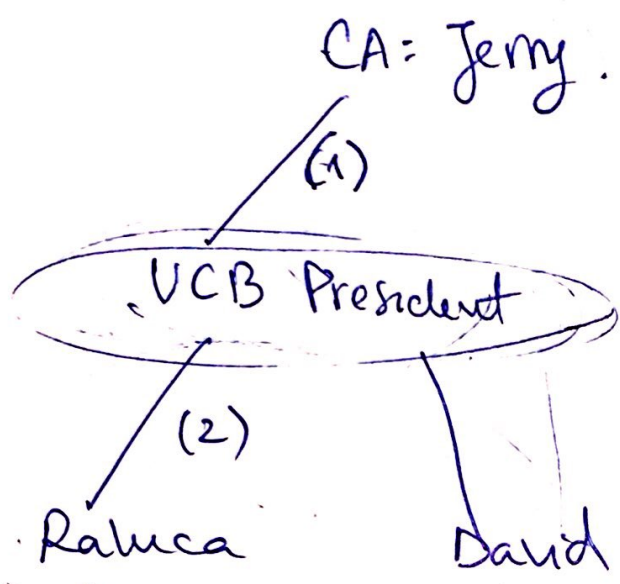

Disadvantages:

→ if SK is compromised, certificate still valid
until expiration

→ mitigation: revocation lists: blacklisted
certificates; browser downloads periodically

→ Scalability: mitigated through hierarchy of certif

Hierarchy PKI

Stanford president

PKCA hardcoded in browsers

Checks chain of certificates
Browser recursively

- (1): $\text{Sign}_{SK_{CA}} ("UCB President has PK_P", \text{expiry})$
- (2): $\text{Sign}_{SK_P} ("Raluca has PK_R", \text{expiry})$
- (3): $\text{Sign}_{SK_R} (\text{Penguin has } PK_{PE}, \text{expiry})$

Certificate chain

Certificate chain gets verified by browser

- browser checks all signatures verify again PK of ~~pro~~ in previous certificate and last PK is PK of CA

Scalable because no one entity issues certificates for everyone

Compromise of SK of entity N in hierarchy can lead to impersonation of all entities underneath N, but no other entities

↓
attacker pretends to be someone they are not

Securing Internet Communication: TLS

CS 161: Computer Security

Prof. Raluca Ada Popa

Feb 22, 2018

Today's Lecture

- Applying crypto technology in practice
- Two simple abstractions cover many use cases for crypto:
 - “Sealed blob”: Data that is encrypted and authenticated under a particular key
 - Secure channel: Communication channel that can't be eavesdropped on or tampered with
- Today: SSL – a secure channel

Today's Lecture

- Goal #1: overview of SSL/TLS, the most prominent Internet security protocol
 - Secures the web via HTTPS
- Goal #2: cement understanding of crypto building blocks & how they're used together

Building Secure End-to-End Channels

- *End-to-end* = communication protections achieved all the way from originating client to **intended** server, between endpoints
 - With no need to trust intermediaries
- Dealing with threats:
 - Eavesdropping?
 - **Encryption** (including session keys)
 - Manipulation (injection, MITM)?
 - **Integrity** (use of a MAC); *replay protection*
 - Impersonation? (someone pretending as you)
 - **Signatures**

(Q: What's missing?
A: Availability ...)

Building A Secure End-to-End Channel: SSL/TLS

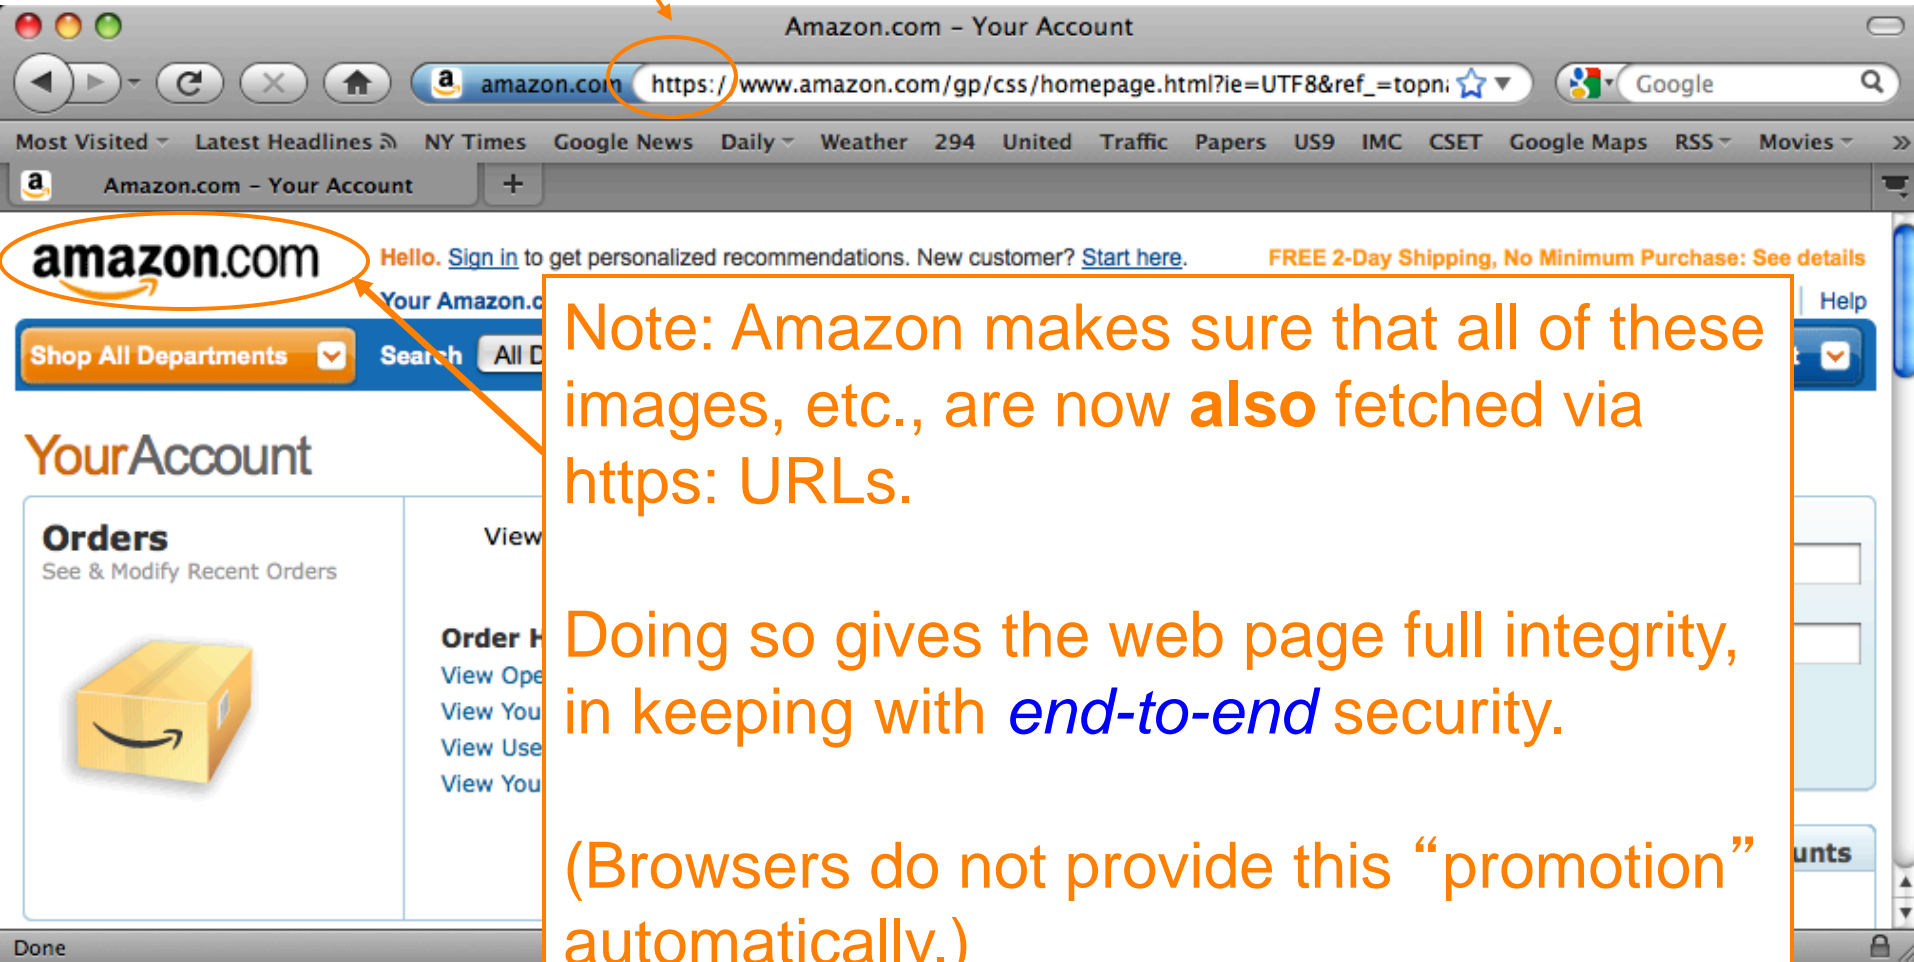

- SSL = *Secure Sockets Layer* (predecessor)
- TLS = *Transport Layer Security* (standard)
 - Both terms used interchangeably
- Security for *any* application that uses TCP
 - Secure = encryption/confidentiality + integrity + authentication (of server, but *not* of client)
 - E.g., puts the ‘s’ in “https”

Regular web surfing - http: URL

The image shows a screenshot of a web browser displaying the Amazon.com homepage. The browser's address bar shows the URL <http://www.amazon.com/>, which is circled in orange. An orange arrow points from the text 'Regular web surfing - http: URL' to this address bar. The Amazon.com logo is visible in the top left. The navigation bar includes links for 'Hello. Sign in to get personalized recommendations. New customer? Start here.', 'Your Amazon.com', 'Today's Deals', 'Gifts & Wish Lists', 'Gift Cards', 'FREE 2-Day Shipping, No Minimum Purchase: See details', 'Your Account', and 'Help'. The 'Your Account' link is circled in orange, with an arrow pointing to it from the text 'But if we click here ...'. Below the navigation bar is a search bar with 'All Departments' selected. On the left, there is a vertical menu with categories like 'Books', 'Movies, Music & Games', 'Digital Downloads', 'Kindle', 'Computers & Office', 'Electronics', 'Home & Garden', 'Grocery, Health & Beauty', 'Toys, Kids & Baby', 'Clothing, Shoes & Jewelry', 'Sports & Outdoors', and 'Tools, Auto & Industrial'. The main content area features a large advertisement for the Kindle, showing a Kindle device displaying 'Chapter 1' and the text 'Kindle You'll Do a Double Take. Reads Like Real Paper, Even in Bright Sunlight.' To the right of the Kindle ad is a wooden lounge chair. Below the chair are three promotional boxes: 'Shop now', 'What's your Pay Phrase? "Strategic Insight" is still available! Claim yours', and 'Warm Your Feet in UGG' with an image of a boot. At the bottom left, there is a status bar that says 'Transferring data from spe.atdmt.com...'

But if we click here ...

Web surfing with TLS/SSL - https: URL

The screenshot shows a web browser window with the title "Amazon.com - Your Account". The address bar displays the URL "https://www.amazon.com/gp/css/homepage.html?ie=UTF8&ref_=topn". The "https://" part of the URL is circled in orange. Below the browser window, a large orange-bordered box contains text explaining that Amazon ensures all content is fetched via https: URLs for security. The text includes a note and a statement about end-to-end security, with a parenthetical note that browsers do not provide this security automatically. The background of the slide shows the Amazon.com website interface, with the "amazon.com" logo circled in orange and an arrow pointing to the text box.

Note: Amazon makes sure that all of these images, etc., are now **also** fetched via https: URLs.

Doing so gives the web page full integrity, in keeping with *end-to-end* security.

(Browsers do not provide this “promotion” automatically.)

RSA Encryption

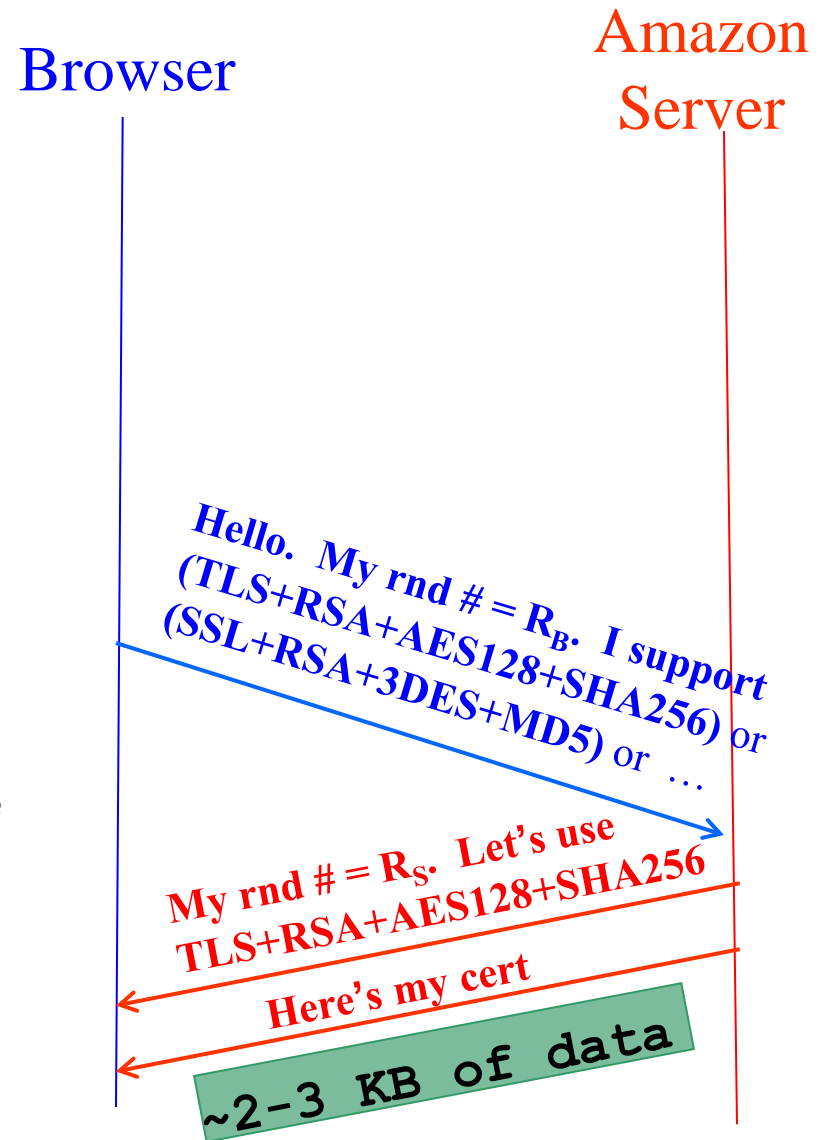

- A public-key encryption algorithm, not only digital signature
- The encrypt algorithm is similar to the verify algorithm, and the decrypt similar to the sign algorithm
- Small differences: encrypt the message with special padding, instead of signing a hash of the message

HTTPS Connection (SSL / TLS)

- Suppose a browser (client) wants to connect to a server **who has a certificate from a trusted CA**
- Client browser and server will exchange symmetric keys using SSL/TLS
- Then, they will send encrypted & authenticated traffic to each other

HTTPS Connection (SSL / TLS)

- Browser (client) connects to Amazon's HTTPS server
- Client picks 256-bit random number R_B , sends over list of crypto algorithms it supports
- Server picks 256-bit random number R_S , selects algorithms to use for this session
- Server sends over its certificate
- (all of this is in the clear)
- ***Client now validates cert***

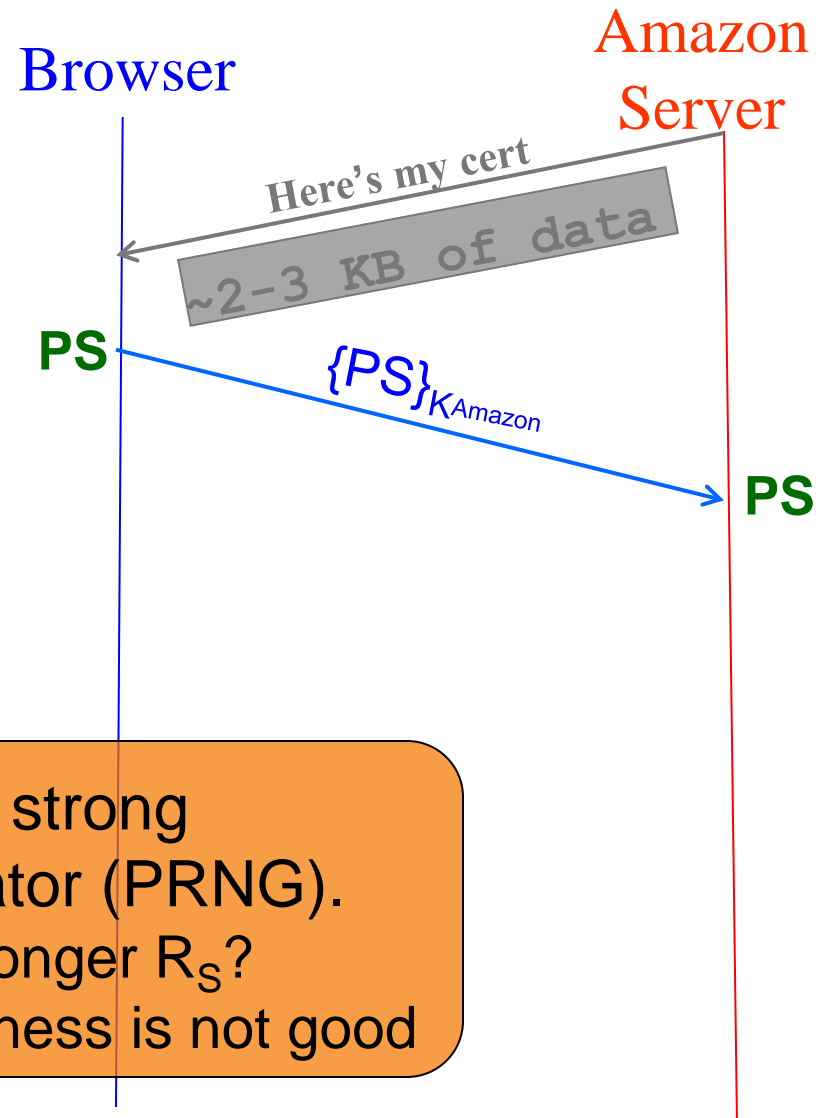

HTTPS Connection (SSL / TLS), cont.

- For RSA, browser constructs “Premaster Secret” **PS**
- Browser sends **PS** encrypted using Amazon’s public RSA key PK_{Amazon}
- Using **PS**, R_B , and R_S , browser & server derive symm. *cipher keys* (C_B , C_S) & MAC *integrity keys* (I_B , I_S)
 - One pair to use in each direction

HTTPS Connection (SSL / TLS), cont.

- For RSA, browser constructs “Premaster Secret” **PS**
- Browser sends **PS** encrypted using Amazon’s public RSA key K_{Amazon}
- Using **PS**, R_B , and R_S , browser & server derive symm. cipher keys (C_B , C_S) & MAC integrity keys (I_B , I_S)
 - One pair to use in each direction

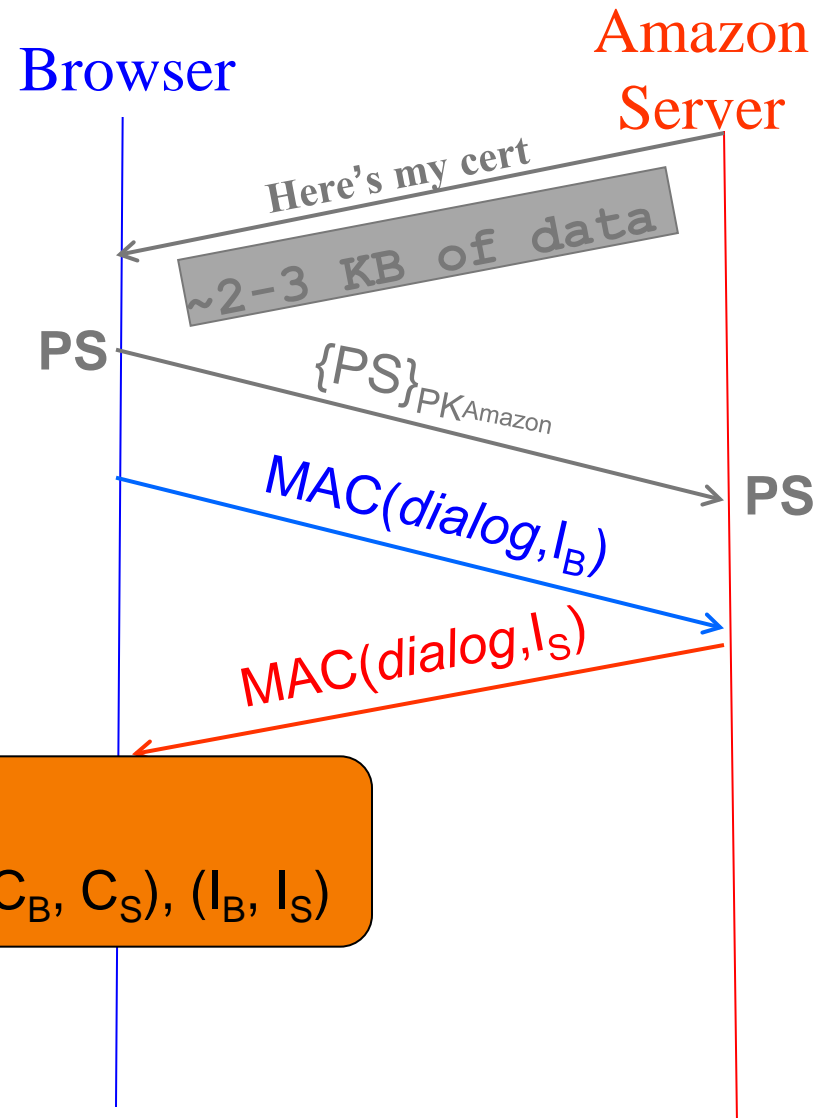

These seed a cryptographically strong pseudo-random number generator (PRNG).

Q: why R_B and R_S , and not just a longer R_S ?

A: just in case one party's randomness is not good

HTTPS Connection (SSL / TLS), cont.

- For RSA, browser constructs “Premaster Secret” **PS**
- Browser sends PS encrypted using Amazon’s public RSA key K_{Amazon}
- Using PS, R_B , and R_S , browser & server derive symm. *cipher keys* (C_B, C_S) & MAC *integrity keys* (I_B, I_S)
 - One pair to use in each direction
- Browser & server exchange MACs computed over entire dialog so far

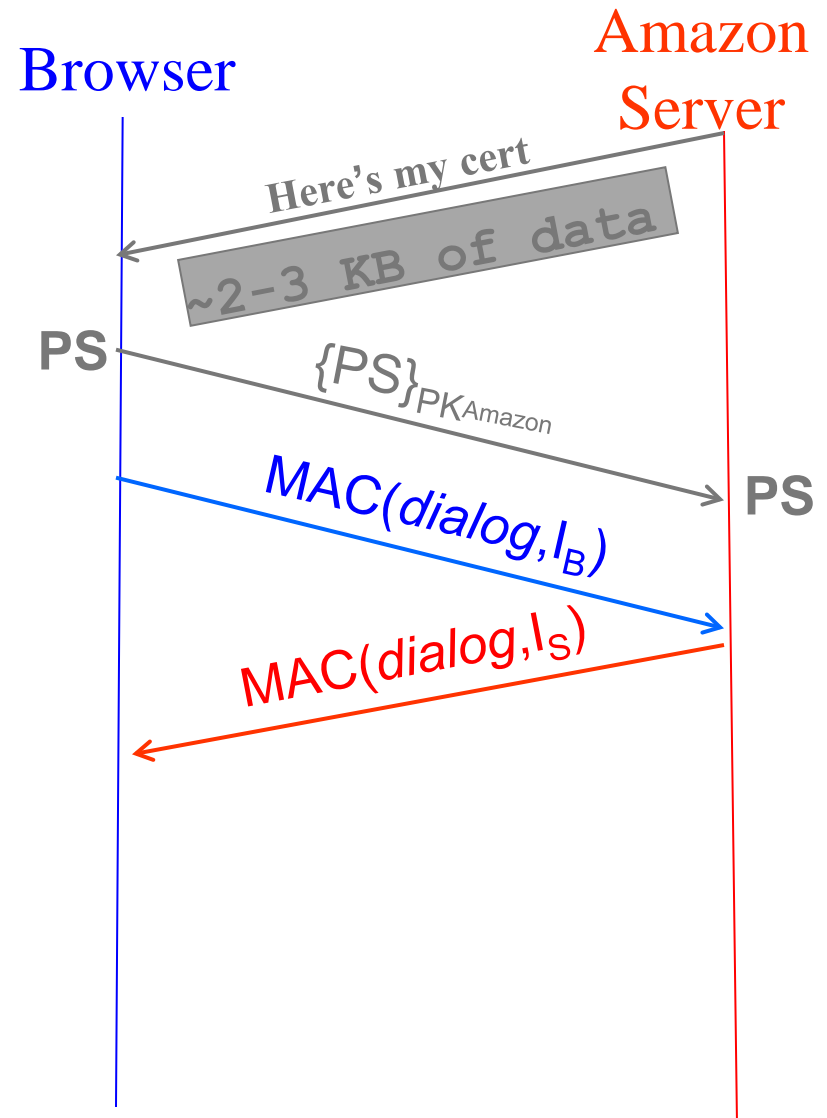

Q: Why?

A: So they know they have same $(C_B, C_S), (I_B, I_S)$

HTTPS Connection (SSL / TLS), cont.

- For RSA, browser constructs “Premaster Secret” PS
- Browser sends PS encrypted using Amazon’s public RSA key K_{Amazon}
- Using PS, R_B , and R_S , browser & server derive *symm. cipher keys* (C_B, C_S) & *MAC integrity keys* (I_B, I_S)
 - One pair to use in each direction
- Browser & server exchange MACs computed over entire dialog so far
- If good MAC, browser displays 

On Firefox:

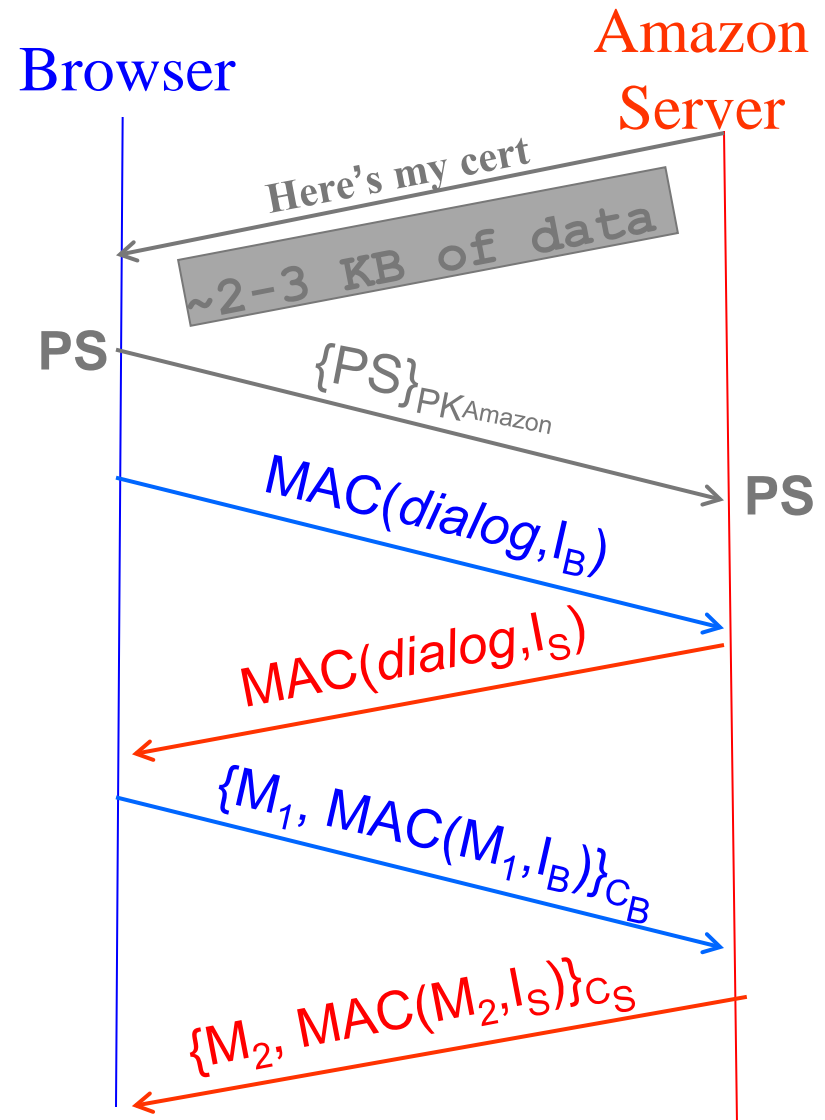

On Chrome:

HTTPS Connection (SSL / TLS), cont.

- For RSA, browser constructs “Premaster Secret” **PS**
- Browser sends PS encrypted using Amazon’s public RSA key K_{Amazon}
- Using PS, R_B , and R_S , browser & server derive *symm. cipher keys* (C_B , C_S) & *MAC integrity keys* (I_B , I_S)
 - One pair to use in each direction
- Browser & server exchange MACs computed over entire dialog so far
- If good MAC, Browser displays 
- All subsequent communication encrypted w/ symmetric cipher (e.g., [AES128](#)) cipher keys in some chaining mode, MACs
 - Sequence #'s included to thwart **replay attacks**

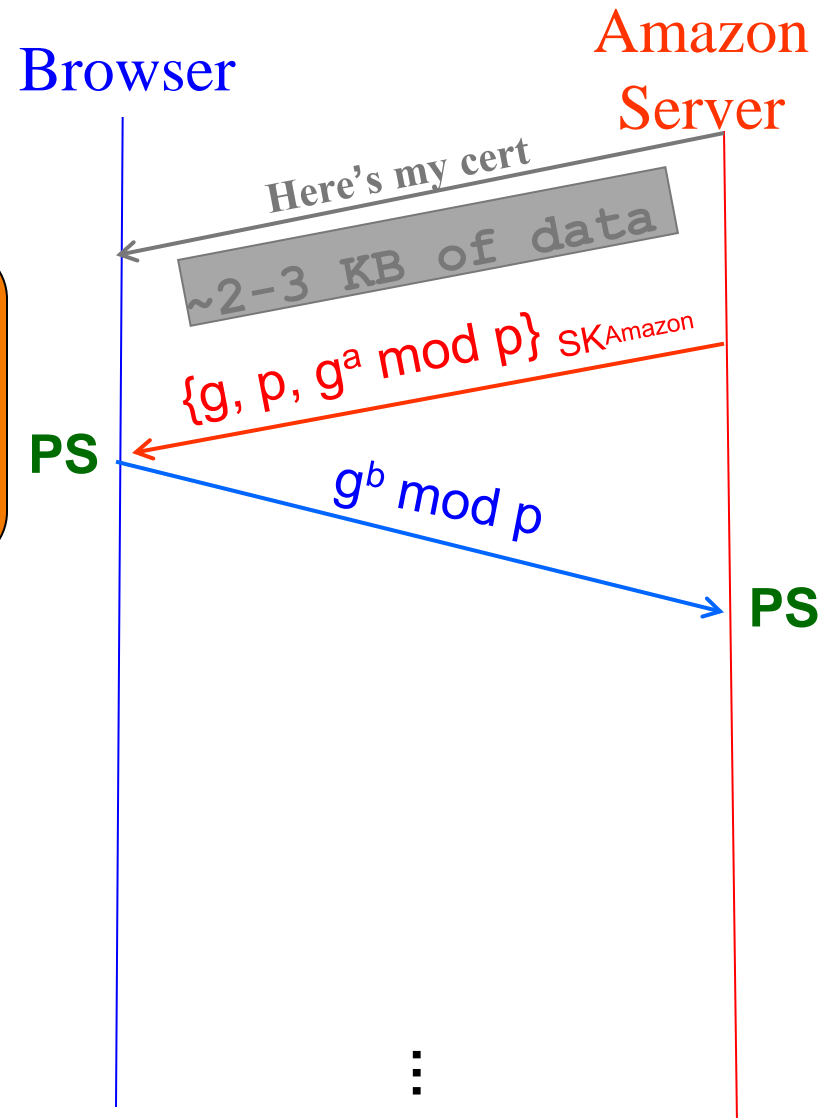

Alternative: Key Exchange via Diffie-Hellman

- For Diffie-Hellman, server generates random a , sends public params and $g^a \bmod p$

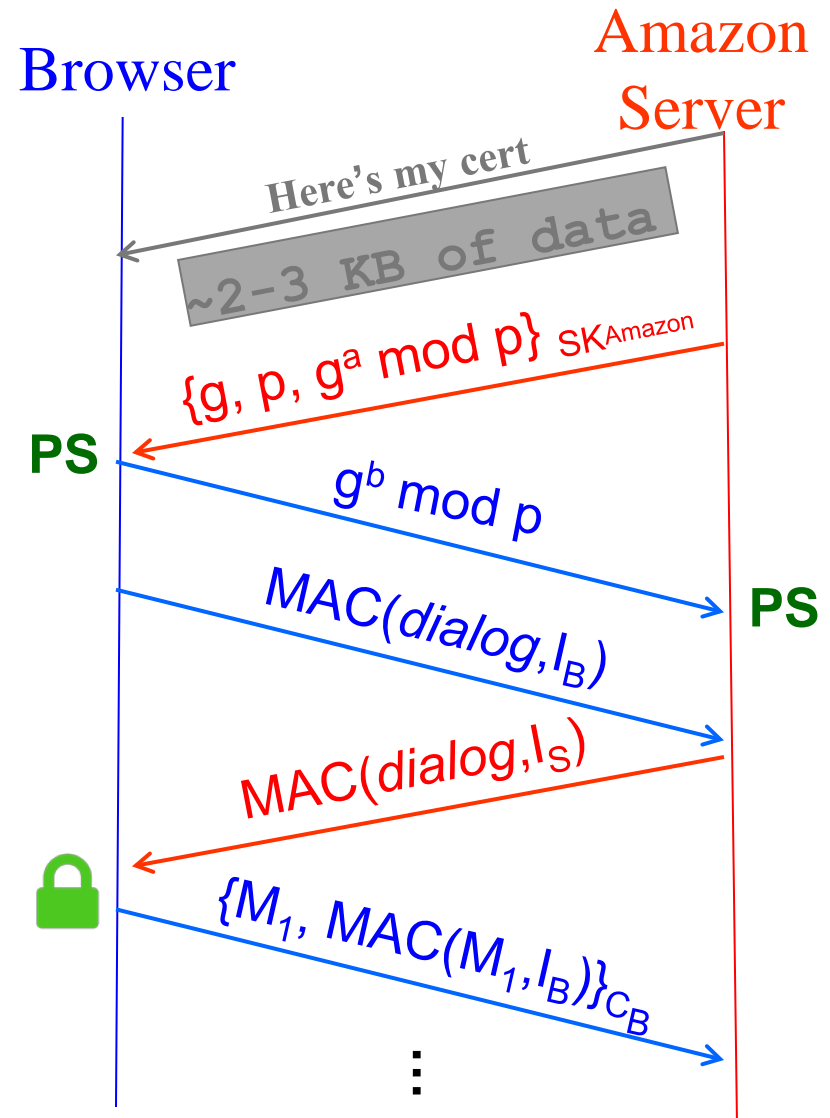

Q: How can we prevent MITM?

A: Server signs $g^a \bmod p$ using SK_{Amazon} , verify using PK_{Amazon} from server certificate

Alternative: Key Exchange via Diffie-Hellman

- For Diffie-Hellman, server generates random a , sends public params and $g^a \bmod p$
 - Signed with server's private key
- Browser verifies signature using PK from certificate
- Browser generates random b , computes $PS = g^{ab} \bmod p$, sends to server
- Server also computes $PS = g^{ab} \bmod p$
- Remainder is as before: from PS , R_B , and R_S , browser & server derive symm. cipher keys (C_B , C_S) and MAC integrity keys (I_B , I_S), etc...

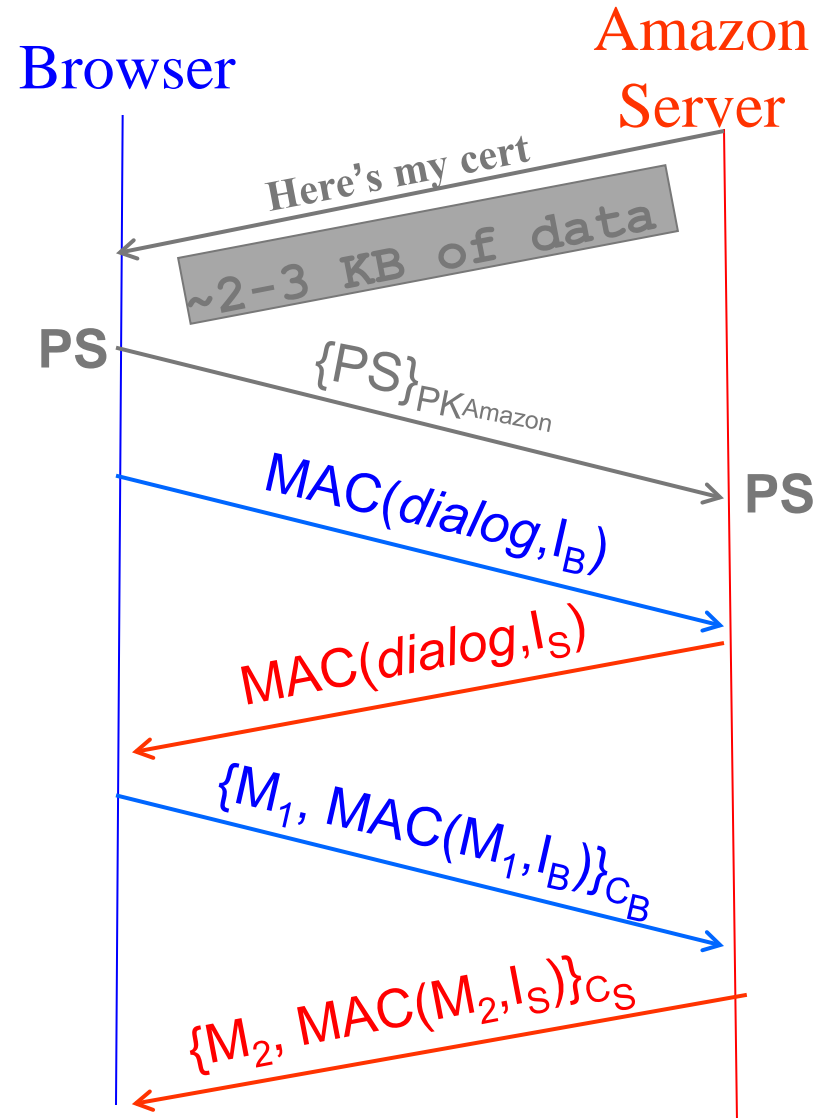

RSA versus Diffie-Hellman

- Forward secrecy: If attacker steals long term secret key of server, SK_{Amazon} , should not be able to read past conversations (cannot compromise past session keys (C_B, C_S) & (I_B, I_S))
- Why matters?
 - Attackers log traffic now. Compromise key in future and try to decrypt the traffic.

Exchange with RSA

Q: Forward secrecy?
A: No forward secrecy because attacker can decrypt PS and knows R_B , and R_S and computes secrets

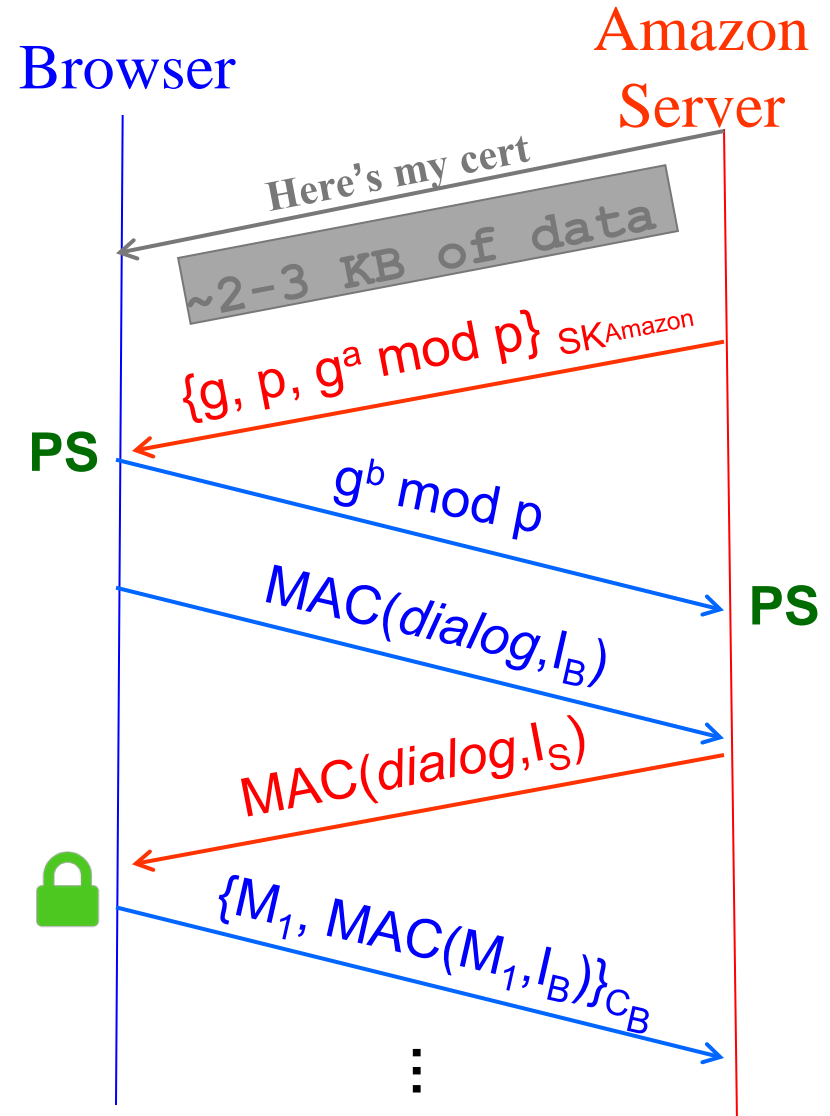

- For RSA, browser constructs “Premaster Secret” **PS**
- Browser sends PS encrypted using Amazon’s public RSA key K_{Amazon}
- Using PS, R_B , and R_S , browser & server derive *symm. cipher keys* (C_B , C_S) & *MAC integrity keys* (I_B , I_S)
 - One pair to use in each direction
- Browser & server exchange MACs computed over entire dialog so far
- If good MAC, Browser displays 
- All subsequent communication encrypted w/ symmetric cipher (e.g., [AES128](#)) cipher keys in some chaining mode, MACs
 - Sequence #'s thwart **replay attacks**

Exchange via Diffie-Hellman

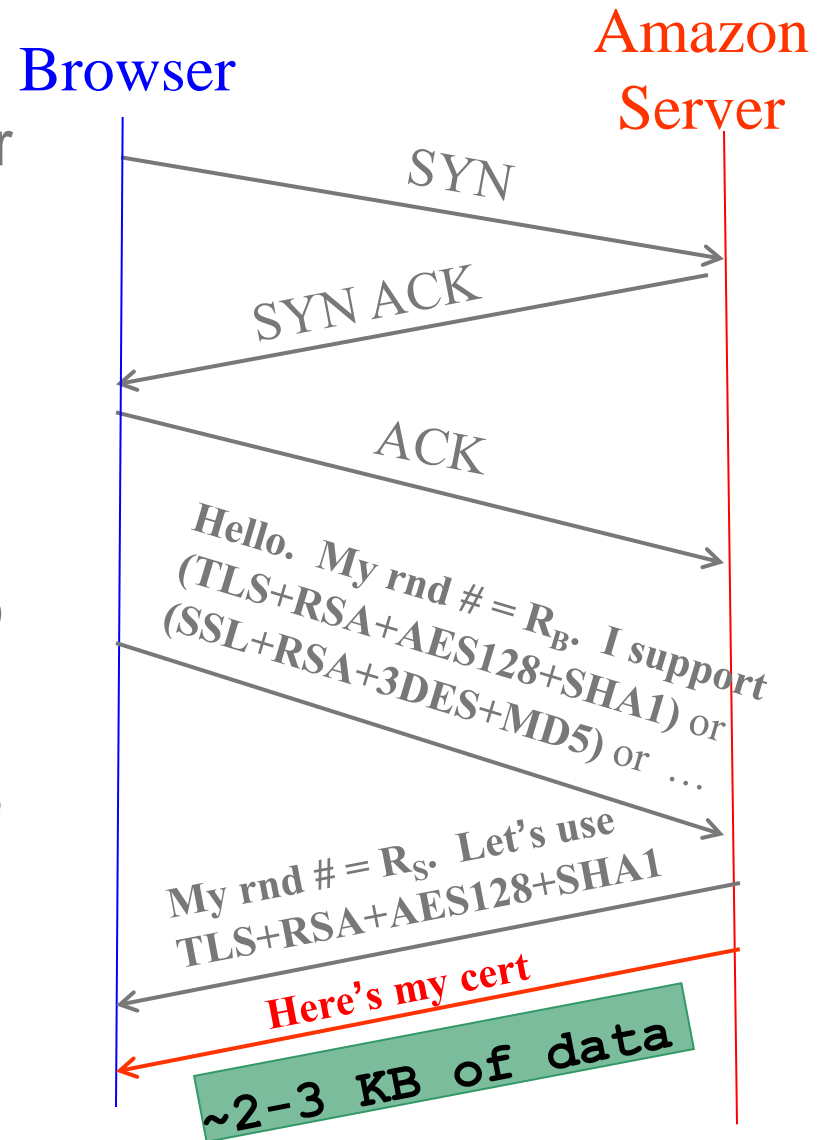

Q: Forward secrecy?
A: Has forward secrecy because shared secret never sent over the network! If attacker has SK_{Amazon} , cannot decrypt a.

- For Diffie-Hellman, server generates random a , sends public params and $g^a \bmod p$
 - Signed with server's private key
- Browser verifies signature using PK from certificate
- Browser generates random b , computes $PS = g^{ab} \bmod p$, sends to server
- Server also computes $PS = g^{ab} \bmod p$
- Remainder is as before: from PS , R_B , and R_S , browser & server derive symm. cipher keys (C_B , C_S) and MAC integrity keys (I_B , I_S), etc...

HTTPS Connection (SSL / TLS)

- Browser (client) connects via TCP to Amazon's HTTPS server
- Client picks 256-bit random number R_B , sends over list of crypto protocols it supports
- Server picks 256-bit random number R_S , selects protocols to use for this session
- Server sends over its certificate
- (all of this is in the clear)
- **Client now validates cert**

Certificates

- Browser compares domain *name* in cert w/ URL
 - Note: this provides an **end-to-end property** (as opposed to say a cert associated with an IP address)
- Browser accesses separate cert belonging to **issuer**
 - These are **hardwired into the browser** – and **trusted!**
 - There could be a **chain** of these ...
- Browser applies issuer's public key to verify signature **S**, obtaining hash of what issuer signed
 - Compares with its own **SHA-256** hash of Amazon's cert
- Assuming hashes match, now have high confidence it's indeed Amazon ...
 - ***assuming signatory is trustworthy***

= assuming didn't lose private key; assuming didn't sign thoughtlessly

End-to-End \Rightarrow Powerful Protections

- Attacker runs a sniffer to capture our WiFi session?
 - (maybe by breaking crummy WEP security)
 - **But:** encrypted communication is unreadable
 - No problem!
- DNS cache poisoning gives client wrong IP address
 - Client goes to wrong server
 - **But:** detects impersonation
 - No problem!
- Attacker hijacks our connection, injects new traffic
 - **But:** data receiver rejects it due to failed integrity check
 - No problem!

Powerful Protections, cont.

- Attacker manipulates routing to run us by an eavesdropper or take us to the wrong server?
 - **But:** they can't read; we detect impersonation
 - **No problem!**
- Attacker slips in as a Man In The Middle?
 - **But:** they can't read, they can't inject
 - They can't even replay previous encrypted traffic
 - **No problem!**

Validating Amazon's Identity, cont.

- Browser retrieves cert belonging to the **issuer**
 - These are hardwired into the browser – and **trusted!**
- What if browser can't find a cert for the issuer?

This Connection is Untrusted

You have asked Firefox to connect securely to **www.mikestoolbox.org**, but we can't confirm that your connection is secure.

Normally, when you try to connect securely, sites will present trusted identification to prove that you are going to the right place. However, this site's identity can't be verified.

What Should I Do?

If you usually connect to this site without problems, this error could mean that someone is trying to impersonate the site, and you shouldn't continue.

Get me out of here!

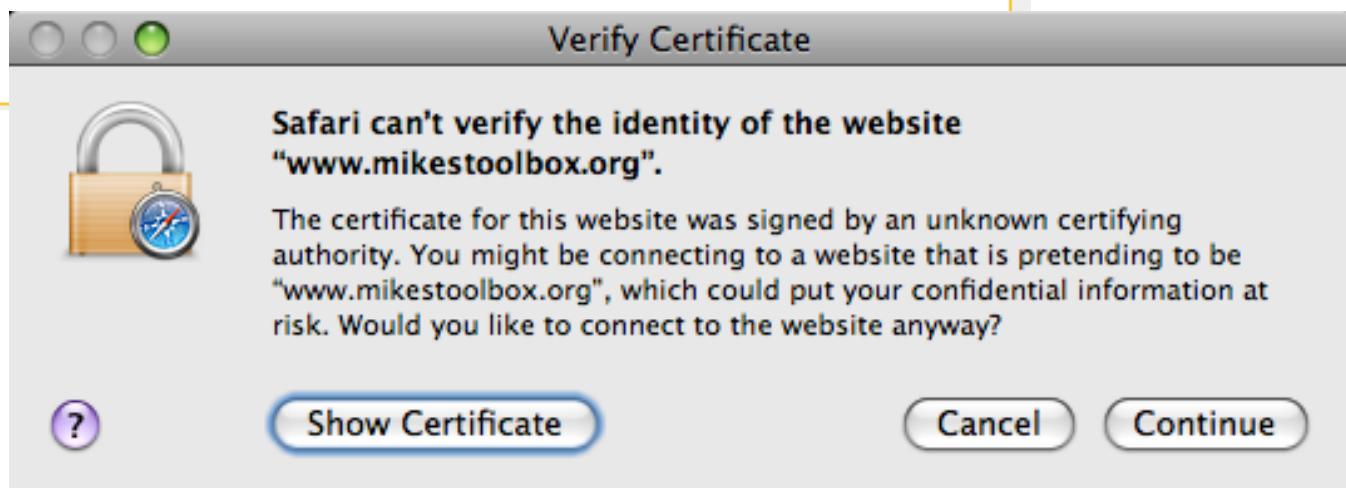

▼ Technical Details

www.mikestoolbox.org uses an invalid security certificate.

The certificate is not trusted because the issuer certificate is not trusted.

(Error code: sec_error_untrusted_issuer)

▶ I Understand the Risks

Validating Amazon's Identity, cont.

- Browser retrieves cert belonging to the **issuer**
 - These are hardwired into the browser – and **trusted!**
- What if browser can't find a cert for the issuer?
- If it can't find the cert, then warns the user that site has not been verified
 - Can still proceed, just **without authentication**
- Q: Which end-to-end security properties do we lose if we incorrectly trust that the site is whom we think?
- A: **All of them!**
 - Goodbye confidentiality, integrity, authentication
 - Man in the middle attacker can read everything, modify, impersonate

SSL / TLS Limitations

- Properly used, SSL / TLS provides powerful end-to-end protections
- So why not use it for *everything*??
- Issues:
 - Cost of public-key crypto (fairly minor)
 - o Takes non-trivial CPU processing (but today a minor issue)
 - o Note: *symmetric* key crypto on modern hardware is non-issue
 - Hassle of buying/maintaining certs (fairly minor)

SSL / TLS Limitations

- Properly used, SSL / TLS provides powerful end-to-end protections
- So why not use it for *everything*??
- Issues:
 - Cost of public-key crypto (fairly minor)
 - o Takes non-trivial CPU processing (but today a minor issue)
 - o Note: *symmetric* key crypto on modern hardware is non-issue
 - Hassle of buying/maintaining certs (fairly minor)
 - Integrating with other sites that don't use HTTPS
 - **Latency**: extra round trips \Rightarrow 1st page slower to load

SSL / TLS Limitations, cont.

- Problems that SSL / TLS does **not** take care of ?
- SQL injection / XSS / server-side coding/logic flaws
- Vulnerabilities introduced by server inconsistencies

Regular web surfing: http: URL

So *no integrity* - a MITM attacker can alter pages returned by server ...

And when we click here ...

... attacker has changed the corresponding link so that it's ordinary http rather than https!

We never get a chance to use TLS's protections! :-)

“sslstrip” attack

SSL / TLS Limitations, cont.

- Problems that SSL / TLS does **not** take care of ?
- SQL injection / XSS / server-side coding/logic flaws
- Vulnerabilities introduced by server inconsistencies
- Browser coding/logic flaws
- User flaws
 - Weak passwords
 - Phishing
- Issues of trust ...

TLS/SSL Trust Issues

- User has to make correct trust decisions ...

Solo Iranian hacker takes credit for Comodo certificate attack

Security researchers split on whether 'ComodoHacker' is the real deal

By Gregg Keizer

March 27, 2011 08:39 PM ET

Comments (5)

Recommended (37)

84

Computerworld - A solo Iranian hacker on Saturday claimed responsibility for stealing multiple SSL certificates belonging to some of the Web's biggest sites, including Google, Microsoft, Skype and Yahoo.

Early reaction from security experts was mixed, with some believing the hacker's claim, while others were dubious.

Last week, conjecture had focused on a state-sponsored attack, perhaps funded or conducted by the Iranian government, that hacked a certificate reseller affiliated with U.S.-based Comodo.

On March 23, Comodo acknowledged the attack, saying that eight days earlier, hackers had obtained nine bogus certificates for the log-on sites of Microsoft's Hotmail, Google's Gmail, the Internet phone and chat service Skype and Yahoo Mail. A certificate for Mozilla's Firefox add-on site was also acquired.

Fraudulent Google certificate points to Internet attack

Is Iran behind a fraudulent Google.com digital certificate? The situation is similar to one that happened in March in which spoofed certificates were traced back to Iran.

by [Elinor Mills](#) | August 29, 2011 1:22 PM PDT

A Dutch company appears to have issued a digital certificate for Google.com to someone other than Google, who may be using it to try to re-direct traffic of users based in Iran.

Yesterday, someone reported on a Google support site that when attempting to log in to Gmail the browser issued a warning for the digital certificate used as proof that the site is legitimate, according to [this thread](#) on a Google support forum site.

October 31, 2012, 10:49AM

Final Report on DigiNotar Hack Shows Total Compromise of CA Servers

The attacker who penetrated the Dutch CA DigiNotar last year had complete control of all eight of the company's certificate-issuing servers during the operation and he may also have issued some rogue certificates that have not yet been identified. The final report from a

Evidence Suggests DigiNotar, Who Issued Fraudulent Google Certificate, Was Hacked *Years Ago*

from the *diginot* dept

The big news in the security world, obviously, is the fact that a **fraudulent Google certificate made its way out into the wild**, apparently targeting internet users in Iran. The Dutch company DigiNotar has put out a statement saying that **it discovered a breach** back on July 19th during a security audit, and that fraudulent certificates were generated for "several dozen" websites. The only one known to have gotten out into the wild is the Google one.

TLS/SSL Trust Issues

- “*Commercial certificate authorities protect you from anyone from whom they are unwilling to take money.*”
 - Matt Blaze, circa 2001
- So how many CAs do we have to worry about, anyway?
- Of course, it’s not just their greed that matters ...
- ... and it’s not just their diligence & security that matters ...
 - “*A decade ago, I observed that commercial certificate authorities protect you from anyone from whom they are unwilling to take money. That turns out to be wrong; they don't even do that much.*” - Matt Blaze, circa 2010

Conclusion

- Use SSL/TLS to secure communications end-to-end
- Relies on trustworthiness of certificates
