Code Generation

Lecture 30 (based on slides by R. Bodik)

Lecture Outline

- Stack machines
- The MIPS assembly language
- The x86 assembly language
- A simple source language
- Stack-machine implementation of the simple language

Stack Machines

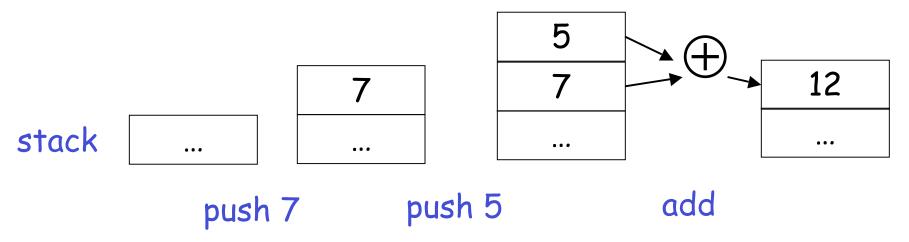

- A simple evaluation model
- No variables or registers
- · A stack of values for intermediate results

Example of a Stack Machine Program

- Consider two instructions
 - push i place the integer i on top of the stack
 - add pop two elements, add them and put
 the result back on the stack
- A program to compute 7 + 5:

```
push 7 push 5 add
```

Stack Machine. Example

- Each instruction:
 - Takes its operands from the top of the stack
 - Removes those operands from the stack
 - Computes the required operation on them
 - Pushes the result on the stack

Why Use a Stack Machine?

- Each operation takes operands from the same place and puts results in the same place
- This means a uniform compilation scheme
- And therefore a simpler compiler

Why Use a Stack Machine?

- · Location of the operands is implicit
 - Always on the top of the stack
- No need to specify operands explicitly
- · No need to specify the location of the result
- Instruction "add" as opposed to "add r_1 , r_2 "
 - ⇒ Smaller encoding of instructions
 - ⇒ More compact programs
- This is one reason why Java Bytecodes use a stack evaluation model

Optimizing the Stack Machine

- · The add instruction does 3 memory operations
 - Two reads and one write to the stack
 - The top of the stack is frequently accessed
- Idea: keep the top of the stack in a register (called accumulator)
 - Register accesses are faster
- The "add" instruction is now

- Only one memory operation!

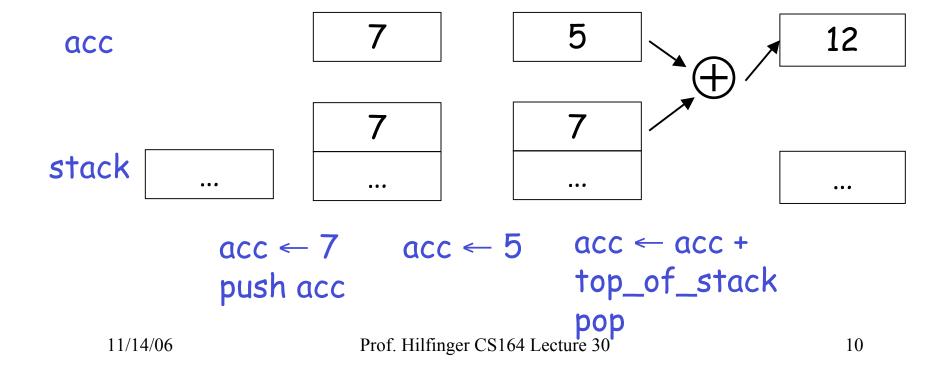

Stack Machine with Accumulator

Invariants

- The result of computing an expression is always in the accumulator
- For an operation $op(e_1,...,e_n)$ push the accumulator on the stack after computing each of $e_1,...,e_{n-1}$
 - The result of e_n is in the accumulator before op
 - After the operation pop n-1 values
- · After computing an expression the stack is as before

Stack Machine with Accumulator. Example

Compute 7 + 5 using an accumulator

A Bigger Example: 3 + (7 + 5)

Code	Acc	Stack
acc ← 3	3	<init></init>
push acc	3	3, <init></init>
acc ← 7	7	3, <init></init>
push acc	7	7, 3, <init></init>
acc ← 5	5	7, 3, <init></init>
acc ← acc + top_of_stac	:k 12	7, 3, <init></init>
pop	12	3, <init></init>
acc ← acc + top_of_stac	:k 15	3, <init></init>
pop	15	<init></init>

Notes

- It is very important that the stack is preserved across the evaluation of a subexpression
 - Stack before the evaluation of 7 + 5 is 3, <init>
 - Stack after the evaluation of 7 + 5 is 3, <init>
 - The first operand is on top of the stack

From Stack Machines to MIPS

- The compiler generates code for a stack machine with accumulator
- We want to run the resulting code on an x86 or MIPS processor (or simulator)
- We implement stack machine instructions using MIPS instructions and registers

MIPS assembly vs. x86 assembly

- In Project 4, you will generate x86 code
 - because we have no MIPS machines around
 - and using a MIPS simulator is less exciting
- · In this lecture, we will use MIPS assembly
 - it's somewhat more readable than x86 assembly
 - e.g. in x86, both store and load are called movl
- translation from MIPS to x86 trivial
 - see the translation table in a few slides

Simulating a Stack Machine...

- The accumulator is kept in MIPS register \$a0
 - in x86, it's in %eax
- The stack is kept in memory
- The stack grows towards lower addresses
 - standard convention on both MIPS and x86
- The address of the next location on the stack is kept in MIPS register \$sp
 - The top of the stack is at address \$sp + 4
 - in x86, it's %esp

MIPS Assembly

MIPS architecture

- Prototypical Reduced Instruction Set Computer (RISC) architecture
- Arithmetic operations use registers for operands and results
- Must use load and store instructions to use operands and results in memory
- 32 general purpose registers (32 bits each)
 - We will use \$sp, \$a0 and \$t1 (a temporary register)

A Sample of MIPS Instructions

```
lw reg₁ offset(reg₂)
Load 32-bit word from address reg₂ + offset into reg₁
add reg₁, reg₂, reg₃
reg₁ ← reg₂ + reg₃
sw reg₁, offset(reg₂)
Store 32-bit word in reg₁ at address reg₂ + offset
addiu reg₁, reg₂, imm
reg₁ ← reg₂ + imm
"u" means overflow is not checked
li reg, imm
reg ← imm
```

x86 Assembly

x86 architecture

- Complex Instruction Set Computer (CISC) architecture
- Arithmetic operations can use both registers and memory for operands and results
- So, you don't have to use separate load and store instructions to operate on values in memory
- CISC gives us more freedom in selecting instructions (hence, more powerful optimizations)
- but we'll use a simple RISC subset of x86
 - so translation from MIPS to x86 will be easy

x86 assembly

- x86 has two-operand instructions:
 - ex.: ADD dest, src dest := dest + src
 - in MIPS: dest := src1 + src2
- An annoying fact to remember
 - different x86 assembly versions exists
 - one important difference: order of operands
 - the manuals assume
 - · ADD dest, src
 - the gcc assembler we'll use uses opposite order
 - · ADD src, dest

Sample x86 instructions (gcc order of operands)

```
movl offset(reg<sub>2</sub>), reg<sub>1</sub>
Load 32-bit word from address reg<sub>2</sub> + offset into reg<sub>1</sub>
add reg<sub>2</sub>, reg<sub>1</sub>
reg<sub>1</sub> ← reg<sub>1</sub> + reg<sub>2</sub>
movl reg<sub>1</sub> offset(reg<sub>2</sub>)
Store 32-bit word in reg<sub>1</sub> at address reg<sub>2</sub> + offset
add imm, reg<sub>1</sub>
reg<sub>1</sub> ← reg<sub>1</sub> + imm
use this for MIPS' addiu
movl imm, reg
reg ← imm
```

MIPS to x86 translation

MIPS	×86
Iw reg_1 , offset(reg_2)	movl offset(reg_2), reg_1
add reg ₁ , reg ₂	add reg ₂ , reg ₁
sw reg ₁ , offset(reg ₂)	movl reg ₁ , offset(reg ₂)
addiu reg ₁ , reg ₁ , imm	add imm, reg ₁
li reg, imm	movl imm, reg

x86 vs. MIPS registers

MIPS	×86
\$aO	%eax
\$sp	%esp
\$fp	%ebp
\$ †	%ebx

MIPS Assembly. Example.

• The stack-machine code for 7 + 5 in MIPS:

```
      acc \leftarrow 7
      li \$a0, 7

      push acc
      sw \$a0, 0(\$sp)

      addiu \$sp, \$sp, -4

      acc \leftarrow 5
      li \$a0, 5

      acc \leftarrow acc + top\_of\_stack
      lw \$t1, 4(\$sp)

      add \$a0, \$a0, \$t1

      pop
      addiu \$sp, \$sp, 4
```

We now generalize this to a simple language...

Some Useful Macros

- We define the following abbreviation
- push \$t

pop

addiu \$sp, \$sp, 4

• \$t ← top

lw \$t, 4(\$sp)

Useful Macros, IA32 version (GNU syntax)

push %t
 pushl %t
 (t a general register)

pop
 addl \$4, %esp
 or
 popl %t (also moves top to %t)

%t ← top movl (%esp), %t

A Small Language

A language with integers and integer operations

```
P \rightarrow D; P \mid D

D \rightarrow def id(ARGS) = E;

ARGS \rightarrow id, ARGS \mid id

E \rightarrow int \mid id \mid if E_1 = E_2 then E_3 else E_4

\mid E_1 + E_2 \mid E_1 - E_2 \mid id(E_1,...,E_n)
```

A Small Language (Cont.)

- The first function definition f is the "main" routine
- Running the program on input i means computing f(i)
- Program for computing the Fibonacci numbers:

```
def fib(x) = if x = 1 then 0 else

if x = 2 then 1 else

fib(x - 1) + fib(x - 2)
```

Code Generation Strategy

- For each expression e we generate MIPS code that:
 - Computes the value of e in \$a0
 - Preserves \$sp and the contents of the stack
- We define a code generation function cgen(e) whose result is the code generated for e

Code Generation for Constants

 The code to evaluate a constant simply copies it into the accumulator:

$$cgen(i) = li $a0, i$$

 Note that this also preserves the stack, as required

Code Generation for Add

```
cgen(e_1 + e_2) =
        cgen(e_1)
        push $a0
        cgen(e_2)
        $t1 \leftarrow top
        add $a0, $t1, $a0
        pop
```

• Possible optimization: Put the result of e_1 directly in register \$11?

Code Generation for Add. Wrong!

Optimization: Put the result of e₁ directly in \$t1?

```
cgen(e_1 + e_2) =
cgen(e_1)
move $11, $a0
cgen(e_2)
add $a0, $11, $a0
```

• Try to generate code for : 3 + (7 + 5)

Code Generation Notes

- The code for + is a template with "holes" for code for evaluating e_1 and e_2
- Stack-machine code generation is recursive
- Code for $e_1 + e_2$ consists of code for e_1 and e_2 glued together
- Code generation can be written as a (modified) post-order traversal of the AST
 - At least for expressions

Code Generation for Sub and Constants

```
• New instruction: sub reg_1 reg_2 reg_3

- Implements reg_1 \leftarrow reg_2 - reg_3

cgen(e_1 - e_2) =

cgen(e_1)

push $a0

cgen(e_2)

$t1 \leftarrow top

sub $a0, $t1, $a0

pop
```

Code Generation for Conditional

- We need flow control instructions
- New instruction: beg reg1, reg2, label
 - Branch to label if $reg_1 = reg_2$
 - x86: cmpl reg₁, reg₂ je label
- New instruction: b label
 - Unconditional jump to label
 - x86: jmp label

Code Generation for If (Cont.)

```
cgen(if e_1 = e_2 then e_3 else e_4) =
 false_branch = new_label()
 true_branch = new_label()
                                        false_branch:
 end_if = new_label()
                                          cgen(e_4)
 cgen(e_1)
                                          b end if
 push $a0
                                        true_branch:
 cgen(e_2)
 $t1 ← top
                                          cgen(e_3)
 pop
                                        end_if:
 beg $a0, $t1, true_branch
```
