Lecture #19: Code Generation		Intermediate Languages and Machine Languages	
[This lecture adopted in part from notes by R. Bodik]		 From trees such as output from project #2, could produce machine language directly. 	
		 However, it is often convenient to first generate some ki mediate language (IL): a "high-level machine language" for machine." 	
		• Advantages:	
		 Separates problem of extracting the operational m dynamic semantics) of a program from the problem o good machine code from it, because it 	
		- Gives a clean target for code generation from the AS	ST.
		 By choosing IL judiciously, we can make the conversion machine language easier than the direct conversion of chine language. Helpful when we want to target sever architectures (e.g., gcc). 	AST ightarrow ma-
		– Likewise, if we can use the same IL for multiple languation re-use the IL $ ightarrow$ machine language implementation (e from Microsoft's Common Language Infrastructure).

Translating from AST to Stack Machin	e	Virtual Register Machines	and Three-Address Code					
 A simple recursive pattern usually serves for expressions. At the top level, our trees might have an expression-code method: 		 Another common kind of virtual machine has an infinite supply of registers, each capable of holding a scalar value or address, in addi- tion to ordinary memory. 						
<pre>class AST { /** Generate code for me, leaving my value on the s virtual void cgen (VM* machine); }</pre>	tack. */		-					
 Implementations of cgen then obey this general commendations assumes that its children will as well. E.g., 	nt, and each		dresses," one destination "address"					
<pre>class BinopNode : public AST { void cgen (VM* machine) { getRight ()->cgen (machine); getLeft ()->cgen (machine); machine->emitInst (translateToInst (getOp ())); } }</pre>		• Often, we require that the operative denote (virtual) registers or imm	ands in the full three-address form ediate (literal) values.					
We assume here a VM is some abstraction of the virt we're producing code for. emitInst adds machine ins the program, and translateToInst converts, e.g., a '+' to Last modified: Wed Oct 31 12:18:49 2012	tructions to	Last modified: Wed Oct 31 12:18:49 2012	C5164: Lecture #19 8					

Three-Address Code, continued

```
• Consider a small language with integers and integer operations:
```

- The first function definition f is the "main" routine
- \bullet Running the program on input i means computing f(i)
- Assume a project-2-like AST.
- \bullet Let's continue implementing cgen ('+' and '-' already done).

```
Conversion of D "," P:
    class StmtListNode : public AST {
        ...
        Operand* cgen (VM* machine) {
            for (int i = 0; i < arity (); i += 1)
               get (i)->cgen (machine);
        }
        return Operand::NoneOperand;
    }
    class IntLiteralNode : public AST {
        ...
        Operand* cgen (VM* machine) {
            return machine->immediateOperand (intTokenValue ());
        }
    }
```

Translating from AST into Three-Address Code

• NoneOperand is an Operand that contains None.

Identifiers

```
class IdNode : public AST {
                                                                                              class CallNode : public AST {
     . . .
                                                                                                 . . .
     Operand* cgen (VM* machine) {
                                                                                                 Operand* cgen (VM* machine) {
        Operand result = machine->allocateRegister ();
                                                                                                    AST* args = getArgList ();
        machine->emitInst (MOVE, result, getDecl()->getMyLocation (machine));
                                                                                                    for (int i = args->arity ()-1; i >= 0; i -= 1)
        return result;
                                                                                                        machine->emitInst (PARAM, args.get (i)->cgen (machine));
     }
                                                                                                    Operand* callable = getCallable ()->cgen (machine);
  }
                                                                                                    machine->emitInst (CALL, callable, args->arity ());
                                                                                                    return Operand::ReturnOperand;
 • That is, we assume that the declaration object holding information
                                                                                                 }
   about this occurrence of the identifier contains its location.
                                                                                              7
                                                                                             • ReturnOperand is abstract location where functions return their
