

IL for Arrays & Local Optimizations

Lecture 26

(Adapted from notes by R. Bodik and G. Necula)

4/23/09

Prof. Hilfinger CS 164 Lecture 26

1

Multi-dimensional Arrays

- A 2D array is a 1D array of 1D arrays
- Java uses arrays of pointers to arrays for >1D arrays.
- But if row size constant, for faster access and compactness, may prefer to represent an $M \times N$ array as a 1D array of 1D rows (not pointers to rows): *row-major order*
- FORTRAN layout is 1D array of 1D columns: *column-major order*.

4/23/09

Prof. Hilfinger CS 164 Lecture 26

2

IL for 2D Arrays (Row-Major Order)

- Again, let S be size of one element, so that a row of length N has size $N \times S$.

```
igen( $e_1[e_2, e_3]$ ,  $t$ ) =  
  igen( $e_1, t_1$ ); igen( $e_2, t_2$ ); igen( $e_3, t_3$ )  
  igen( $N, t_4$ )    ( $N$  need not be constant)  
 $t_5 := t_4 * t_2$ ;  $t_6 := t_5 + t_3$ ;  
 $t_7 := t_6 * S$ ;  
 $t_8 := t_7 + t_1$   
 $t := *t_8$ 
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

3

Array Descriptors

- Calculation of element address for $e_1[e_2, e_3]$ has form $VO + S_1 \times e_2 + S_2 \times e_3$, where
 - VO (address of $e_1[0,0]$) is the *virtual origin*
 - S_1 and S_2 are *strides*
 - All three of these are constant throughout lifetime of array
- Common to package these up into an *array descriptor*, which can be passed in lieu of the array itself.

4/23/09

Prof. Hilfinger CS 164 Lecture 26

4

Array Descriptors (II)

- By judicious choice of descriptor values, can make the same formula work for different kinds of array.
- For example, if lower bounds of indices are 1 rather than 0, must compute
$$\text{address of } e[1,1] + S_1 \times (e_2 - 1) + S_2 \times (e_3 - 1)$$
- But some algebra puts this into the form
$$VO + S_1 \times e_2 + S_2 \times e_3$$

where $VO = \text{address of } e[1,1] - S_1 - S_2$

4/23/09

Prof. Hilfinger CS 164 Lecture 26

5

Observation

- These examples show profligate use of registers.
- Doesn't matter, because this is Intermediate Code. Rely on later optimization stages to do the right thing.

4/23/09

Prof. Hilfinger CS 164 Lecture 26

6

Code Optimization: Basic Concepts

4/23/09

Prof. Hilfinger CS 164 Lecture 26

7

Definition. Basic Blocks

- A *basic block* is a maximal sequence of instructions with:
 - no labels (except at the first instruction), and
 - no jumps (except in the last instruction)
- Idea:
 - Cannot jump in a basic block (except at beginning)
 - Cannot jump out of a basic block (except at end)
 - Each instruction in a basic block is executed after all the preceding instructions have been executed

4/23/09

Prof. Hilfinger CS 164 Lecture 26

8

Basic Block Example

- Consider the basic block
 1. L:
 2. $t := 2 * x$
 3. $w := t + x$
 4. `if $w > 0$ goto L'`
- No way for (3) to be executed without (2) having been executed right before
 - We can change (3) to $w := 3 * x$
 - Can we eliminate (2) as well?

4/23/09

Prof. Hilfinger CS 164 Lecture 26

9

Definition. Control-Flow Graphs

- A *control-flow graph* is a directed graph with
 - Basic blocks as nodes
 - An edge from block A to block B if the execution can flow from the last instruction in A to the first instruction in B
 - E.g., the last instruction in A is `jump L_B`
 - E.g., the execution can fall-through from block A to block B
- Frequently abbreviated as CFG

4/23/09

Prof. Hilfinger CS 164 Lecture 26

10

Control-Flow Graphs. Example.

- The body of a method (or procedure) can be represented as a control-flow graph
- There is one initial node
- All "return" nodes are terminal

4/23/09

Prof. Hilfinger CS 164 Lecture 26

11

Optimization Overview

- Optimization seeks to improve a program's utilization of some resource
 - Execution time (most often)
 - Code size
 - Network messages sent
 - Battery power used, etc.
- Optimization should not alter what the program computes
 - The answer must still be the same

4/23/09

Prof. Hilfinger CS 164 Lecture 26

12

A Classification of Optimizations

- For languages like *C* and *Cool* there are three granularities of optimizations
 1. Local optimizations
 - Apply to a basic block in isolation
 2. Global optimizations
 - Apply to a control-flow graph (method body) in isolation
 3. Inter-procedural optimizations
 - Apply across method boundaries
- Most compilers do (1), many do (2) and very few do (3)

4/23/09

Prof. Hilfinger CS 164 Lecture 26

13

Cost of Optimizations

- In practice, a conscious decision is made not to implement the fanciest optimization known
- Why?
 - Some optimizations are hard to implement
 - Some optimizations are costly in terms of compilation time
 - The fancy optimizations are both hard and costly
- The goal: maximum improvement with minimum of cost

4/23/09

Prof. Hilfinger CS 164 Lecture 26

14

Local Optimizations

- The simplest form of optimizations
- No need to analyze the whole procedure body
 - Just the basic block in question
- Example: algebraic simplification

4/23/09

Prof. Hilfinger CS 164 Lecture 26

15

Algebraic Simplification

- Some statements can be deleted
 - $x := x + 0$
 - $x := x * 1$
- Some statements can be simplified
 - $x := x * 0 \Rightarrow x := 0$
 - $y := y ** 2 \Rightarrow y := y * y$
 - $x := x * 8 \Rightarrow x := x \ll 3$
 - $x := x * 15 \Rightarrow \dagger := x \ll 4; x := \dagger - x$

(on some machines \ll is faster than $*$; but not on all!)

4/23/09

Prof. Hilfinger CS 164 Lecture 26

16

Constant Folding

- Operations on constants can be computed at compile time
- In general, if there is a statement
 - $x := y \text{ op } z$
 - And y and z are constants
 - Then $y \text{ op } z$ can be computed at compile time
- Example: $x := 2 + 2 \Rightarrow x := 4$
- Example: $\text{if } 2 < 0 \text{ jump } L$ can be deleted
- When might constant folding be dangerous?

4/23/09

Prof. Hilfinger CS 164 Lecture 26

17

Flow of Control Optimizations

- Eliminating unreachable code:
 - Code that is unreachable in the control-flow graph
 - Basic blocks that are not the target of any jump or "fall through" from a conditional
 - Such basic blocks can be eliminated
- Why would such basic blocks occur?
- Removing unreachable code makes the program smaller
 - And sometimes also faster, due to memory cache effects (increased spatial locality)

4/23/09

Prof. Hilfinger CS 164 Lecture 26

18

Single Assignment Form

- Some optimizations are simplified if each assignment is to a temporary that has not appeared already in the basic block
- Intermediate code can be rewritten to be in single assignment form

```
x := a + y      x := a + y
a := x          a1 := x
x := a * x      x1 := a1 * x
b := x + a      b := x1 + a1
                (x1 and a1 are fresh temporaries)
```

4/23/09

Prof. Hillfinger CS 164 Lecture 26

19

Common Subexpression Elimination

- Assume
 - Basic block is in *single assignment form*
- All assignments with same rhs compute the same value
- Example:

```
x := y + z      x := y + z
...            ...
w := y + z      w := x
```
- Why is single assignment important here?

4/23/09

Prof. Hillfinger CS 164 Lecture 26

20

Copy Propagation

- If $w := x$ appears in a block, all subsequent uses of w can be replaced with uses of x
- Example:

```
b := z + y      b := z + y
a := b          a := b
x := 2 * a      x := 2 * b
```
- This does not make the program smaller or faster but might enable other optimizations
 - Constant folding
 - Dead code elimination
- Again, single assignment is important here.

4/23/09

Prof. Hillfinger CS 164 Lecture 26

21

Copy Propagation and Constant Folding

- Example:

```
a := 5          a := 5
x := 2 * a      x := 10
y := x + 6      y := 16
t := x * y      t := x << 4
```

4/23/09

Prof. Hillfinger CS 164 Lecture 26

22

Dead Code Elimination

If $w := rhs$ appears in a basic block
 w does not appear anywhere else in the program
Then the statement $w := rhs$ is dead and can be eliminated
- Dead = does not contribute to the program's result

Example: (a is not used anywhere else)

```
x := z + y      b := z + y      b := z + y
a := x          a := b          x := 2 * b
x := 2 * a      x := 2 * b
```

4/23/09

Prof. Hillfinger CS 164 Lecture 26

23

Applying Local Optimizations

- Each local optimization does very little by itself
- Typically optimizations interact
 - Performing one optimizations enables other opt.
- Typical optimizing compilers repeatedly perform optimizations until no improvement is possible
 - The optimizer can also be stopped at any time to limit the compilation time

4/23/09

Prof. Hillfinger CS 164 Lecture 26

24

An Example

- Initial code:

```
a := x ** 2
b := 3
c := x
d := c * c
e := b * 2
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

25

An Example

- Algebraic optimization:

```
a := x ** 2
b := 3
c := x
d := c * c
e := b * 2
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

26

An Example

- Algebraic optimization:

```
a := x * x
b := 3
c := x
d := c * c
e := b + b
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

27

An Example

- Copy propagation:

```
a := x * x
b := 3
c := x
d := c * c
e := b + b
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

28

An Example

- Copy propagation:

```
a := x * x
b := 3
c := x
d := x * x
e := 3 + 3
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

29

An Example

- Constant folding:

```
a := x * x
b := 3
c := x
d := x * x
e := 3 + 3
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

30

An Example

- Constant folding:

```
a := x * x
b := 3
c := x
d := x * x
e := 6
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

31

An Example

- Common subexpression elimination:

```
a := x * x
b := 3
c := x
d := x * x
e := 6
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

32

An Example

- Common subexpression elimination:

```
a := x * x
b := 3
c := x
d := a
e := 6
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

33

An Example

- Copy propagation:

```
a := x * x
b := 3
c := x
d := a
e := 6
f := a + d
g := e * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

34

An Example

- Copy propagation:

```
a := x * x
b := 3
c := x
d := a
e := 6
f := a + a
g := 6 * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

35

An Example

- Dead code elimination:

```
a := x * x
b := 3
c := x
d := a
e := 6
f := a + a
g := 6 * f
```

4/23/09

Prof. Hilfinger CS 164 Lecture 26

36

An Example

- Dead code elimination:

```
a := x * x
```

```
f := a + a  
g := 6 * f
```

- This is the final form

4/23/09

Prof. Hillfinger CS 164 Lecture 26

37

Peephole Optimizations on Assembly Code

- The optimizations presented before work on intermediate code
 - They are target independent
 - But they can be applied on assembly language also
- *Peephole optimization* is an effective technique for improving assembly code
 - The "peephole" is a short sequence of (usually contiguous) instructions
 - The optimizer replaces the sequence with another equivalent (but faster) one

4/23/09

Prof. Hillfinger CS 164 Lecture 26

38

Peephole Optimizations (Cont.)

- Write peephole optimizations as replacement rules

```
 $i_1, \dots, i_n \rightarrow j_1, \dots, j_m$ 
```

where the rhs is the improved version of the lhs

- Examples:

```
move $a $b, move $b $a → move $a $b
```

- Works if `move $b $a` is not the target of a jump

```
addiu $a $b k, lw $c ($a) → lw $c k($b)
```

- Works if `$a` not used later (is "dead")

4/23/09

Prof. Hillfinger CS 164 Lecture 26

39

Peephole Optimizations (Cont.)

- Many (but not all) of the basic block optimizations can be cast as peephole optimizations
 - Example: `addiu $a $b 0 → move $a $b`
 - Example: `move $a $a →`
 - These two together eliminate `addiu $a $a 0`
- Just like for local optimizations, peephole optimizations need to be applied repeatedly to get maximum effect

4/23/09

Prof. Hillfinger CS 164 Lecture 26

40

Local Optimizations. Notes.

- Intermediate code is helpful for many optimizations
- Many simple optimizations can still be applied on assembly language
- "Program optimization" is grossly misnamed
 - Code produced by "optimizers" is not optimal in any reasonable sense
 - "Program improvement" is a more appropriate term

4/23/09

Prof. Hillfinger CS 164 Lecture 26

41

Local Optimizations. Notes (II).

- Serious problem: what to do with pointers?
 - `*t` may change even if local variable `t` does not:
Aliasing
 - Arrays are a special case (address calculation)
- What to do about globals?
- What to do about calls?
 - Not exactly jumps, because they (almost) always return.
 - Can modify variables used by caller
- Next: global optimizations

4/23/09

Prof. Hillfinger CS 164 Lecture 26

42
