

Global Optimization

Lecture 27
(From notes by R. Bodik & G. Necula)

4/28/09

Prof. Hilfinger CS164 Lecture 27

1

Administrative

- HW #6 was posted online this evening.
- Version #2 of project 3 files: representation now complete, but still a bit of work for me to do.

4/28/09

Prof. Hilfinger CS164 Lecture 27

2

Lecture Outline

- Global flow analysis
- Global constant propagation
- Liveness analysis

4/28/09

Prof. Hilfinger CS164 Lecture 27

3

Local Optimization

Simple basic-block optimizations...

- Constant propagation
- Dead code elimination

```
X := 3           X := 3           X := 3
Y := Z * W       Y := Z * W       Y := Z * W
Q := X + Y       Q := 3 + Y       Q := 3 + Y
```

4/28/09

Prof. Hilfinger CS164 Lecture 27

4

Global Optimization

... extend to entire control-flow graphs

4/28/09

Prof. Hilfinger CS164 Lecture 27

5

Global Optimization

... extend to entire control-flow graphs

4/28/09

Prof. Hilfinger CS164 Lecture 27

6

Global Optimization

... extend to entire control-flow graphs

4/28/09

Prof. Hilfinger CS164 Lecture 27

7

Correctness

- How do we know it is OK to globally propagate constants?
- There are situations where it is incorrect:

4/28/09

Prof. Hilfinger CS164 Lecture 27

8

Correctness (Cont.)

To replace a use of x by a constant k we must know that:

Constant Replacement Condition (CR):

On every path to the use of x , the last assignment to x is $x := k$

4/28/09

Prof. Hilfinger CS164 Lecture 27

9

Example 1 Revisited

so replacing X by 3 is OK

4/28/09

Prof. Hilfinger CS164 Lecture 27

10

Example 2 Revisited

so replacing X by 3 is **not** OK

4/28/09

Prof. Hilfinger CS164 Lecture 27

11

Discussion

- The correctness condition is not trivial to check
- "All paths" includes paths around loops and through branches of conditionals
- Checking the condition requires global analysis
 - An analysis of the entire control-flow graph for one method body

4/28/09

Prof. Hilfinger CS164 Lecture 27

12

Global Analysis

Global optimization tasks share several traits:

- The optimization depends on knowing a property P at a particular point in program execution
- Proving P at any point requires knowledge of the entire method body
- Property P is typically undecidable !

4/28/09

Prof. Hilfinger CS164 Lecture 27

13

Undecidability of Program Properties

- Rice's theorem: Most interesting dynamic properties of a program are undecidable:
 - Does the program halt on all (some) inputs?
 - This is called the halting problem
 - Is the result of a function F always positive?
 - Assume we can answer this question precisely
 - Take function H and find out if it halts by testing function $F(x) \{ H(x); \text{return } 1; \}$ whether it has positive result
- Syntactic properties are decidable !
 - E.g., How many occurrences of " x " are there?
- Theorem does not apply in absence of loops

4/28/09

Prof. Hilfinger CS164 Lecture 27

14

Conservative Program Analyses

- So, we cannot tell for sure that " x " is always 3
 - Then, how can we apply constant propagation?
- It is OK to be *conservative*. If the optimization requires P to be true, then want to know either
 - P is definitely true
 - Don't know if P is true or false
- It is always correct to say "don't know"
 - We try to say don't know as rarely as possible
- All program analyses are conservative

4/28/09

Prof. Hilfinger CS164 Lecture 27

15

Global Analysis (Cont.)

- *Global dataflow analysis* is a standard technique for solving problems with these characteristics
- Global constant propagation is one example of an optimization that requires global dataflow analysis

4/28/09

Prof. Hilfinger CS164 Lecture 27

16

Global Constant Propagation

- Global constant propagation can be performed at any point where *CR condition* holds
- Consider the case of computing *CR condition* for a single variable X at all program points

4/28/09

Prof. Hilfinger CS164 Lecture 27

17

Global Constant Propagation (Cont.)

- To make the problem precise, we associate one of the following values with X at every program point

| value | interpretation |
|-------|---------------------------------|
| # | No value has reached here (yet) |
| c | $X = \text{constant } c$ |
| * | Don't know if X is a constant |

4/28/09

Prof. Hilfinger CS164 Lecture 27

18

Example

4/28/09

Prof. Hilfinger CS164 Lecture 27

19

Using the Information

- Given global constant information, it is easy to perform the optimization
 - Simply inspect the $x = _$ associated with a statement using x
 - If x is constant at that point replace that use of x by the constant
- But how do we compute the properties $x = _$

4/28/09

Prof. Hilfinger CS164 Lecture 27

20

The Idea

The analysis of a complicated program can be expressed as a combination of simple rules relating the change in information between adjacent statements

4/28/09

Prof. Hilfinger CS164 Lecture 27

21

Explanation

- The idea is to "push" or "transfer" information from one statement to the next
- For each statement s , we compute information about the value of x immediately before and after s

$C_{in}(x, s)$ = value of x before s

$C_{out}(x, s)$ = value of x after s

(we care about values $\#, *, k$)

4/28/09

Prof. Hilfinger CS164 Lecture 27

22

Transfer Functions

- Define a *transfer function* that transfers information from one statement to another
- In the following rules, let statement s have immediate predecessor statements p_1, \dots, p_n

4/28/09

Prof. Hilfinger CS164 Lecture 27

23

Rule 1

if $C_{out}(x, p_i) = *$ for some i , then $C_{in}(x, s) = *$

4/28/09

Prof. Hilfinger CS164 Lecture 27

24

Rule 2

If $C_{out}(x, p_i) = c$ and $C_{out}(x, p_j) = d$ and $d \neq c$
then $C_{in}(x, s) = *$

4/28/09

Prof. Hilfinger CS164 Lecture 27

25

Rule 3

if $C_{out}(x, p_i) = c$ for at least one i and is c or $\#$
for all i , then $C_{in}(x, s) = c$

4/28/09

Prof. Hilfinger CS164 Lecture 27

26

Rule 4

if $C_{out}(x, p_i) = \#$ for all i ,
then $C_{in}(x, s) = \#$

4/28/09

Prof. Hilfinger CS164 Lecture 27

27

The Other Half

- Rules 1-4 relate the *out* of one statement to the *in* of the successor statement
 - they propagate information *forward* across CFG edges
- Now we need rules relating the *in* of a statement to the *out* of the same statement
 - to propagate information across statements

4/28/09

Prof. Hilfinger CS164 Lecture 27

28

Rule 5

$C_{out}(x, s) = \#$ if $C_{in}(x, s) = \#$

4/28/09

Prof. Hilfinger CS164 Lecture 27

29

Rule 6

$C_{out}(x, x := c) = c$ if c is a constant

4/28/09

Prof. Hilfinger CS164 Lecture 27

30

Rule 7

$$C_{out}(x, x := f(\dots)) = *$$

4/28/09

Prof. Hilfinger CS164 Lecture 27

31

Rule 8

$$C_{out}(x, y := \dots) = C_{in}(x, y := \dots) \text{ if } x \neq y$$

4/28/09

Prof. Hilfinger CS164 Lecture 27

32

An Algorithm

1. For every entry s to the program, set $C_{in}(x, s) = *$
2. Set $C_{in}(x, s) = C_{out}(x, s) = \#$ everywhere else
3. Repeat until all points satisfy 1-8:
Pick s not satisfying 1-8 and update using the appropriate rule

4/28/09

Prof. Hilfinger CS164 Lecture 27

33

The Value

- To understand why we need $\#$, look at a loop

4/28/09

Prof. Hilfinger CS164 Lecture 27

34

The Value # (Cont.)

- Consider the statement $Y := 0$
- To compute whether X is constant at this point, we need to know whether X is constant at the two predecessors
 - $X := 3$
 - $A := 2 * X$
- But info for $A := 2 * X$ depends on its predecessors, including $Y := 0$!

4/28/09

Prof. Hilfinger CS164 Lecture 27

35

The Value # (Cont.)

- Because of cycles, all points must have values at all times
- Intuitively, assigning some initial value allows the analysis to break cycles
- The initial value $\#$ means "So far as we know, control never reaches this point"

4/28/09

Prof. Hilfinger CS164 Lecture 27

36

Example

We are done when all rules are satisfied!

4/28/09 Prof. Hilfinger CS164 Lecture 27 37

Another Example

4/28/09 Prof. Hilfinger CS164 Lecture 27 38

Another Example

Must continue until all rules are satisfied!

4/28/09 Prof. Hilfinger CS164 Lecture 27 39

Orderings

- We can simplify the presentation of the analysis by ordering the values
 $\# < c < *$
- Drawing a picture with "smaller" values drawn lower, we get

a lattice

4/28/09 Prof. Hilfinger CS164 Lecture 27 40

Orderings (Cont.)

- * is the largest value, # is the least
 - All constants are in between and incomparable
- Let *lub* be the least-upper bound in this ordering
- Rules 1-4 can be written using lub:
 $C_{in}(x, s) = \text{lub} \{ C_{out}(x, p) \mid p \text{ is a predecessor of } s \}$

4/28/09 Prof. Hilfinger CS164 Lecture 27 41

Termination

- Simply saying "repeat until nothing changes" doesn't guarantee that eventually nothing changes
- The use of lub explains why the algorithm terminates
 - Values start as # and only increase
 - # can change to a constant, and a constant to *
 - Thus, $C_{in}(x, s)$ can change at most twice

4/28/09 Prof. Hilfinger CS164 Lecture 27 42

Termination (Cont.)

Thus the algorithm is linear in program size

- Number of steps
- = Number of C_{\dots} values computed * 2
- = Number of program statements * 4

4/28/09

Prof. Hilfinger CS164 Lecture 27

43

Liveness Analysis

Once constants have been globally propagated, we would like to eliminate dead code

After constant propagation, $X := 3$ is dead (assuming this is the entire CFG)

4/28/09

Prof. Hilfinger CS164 Lecture 27

44

Live and Dead

- The first value of x is *dead* (never used)
- The second value of x is *live* (may be used)

4/28/09

Prof. Hilfinger CS164 Lecture 27

45

Liveness

A variable x is *live at statement s* if

- There exists a statement s' that uses x
- There is a path from s to s'
- That path has no intervening assignment to x

4/28/09

Prof. Hilfinger CS164 Lecture 27

46

Global Dead Code Elimination

- A statement $x := \dots$ is dead code if x is dead after the assignment
- Dead statements can be deleted from the program
- But we need liveness information first . . .

4/28/09

Prof. Hilfinger CS164 Lecture 27

47

Computing Liveness

- We can express liveness as a function of information transferred between adjacent statements, just as in copy propagation
- Liveness is simpler than constant propagation, since it is a boolean property (true or false)

4/28/09

Prof. Hilfinger CS164 Lecture 27

48

Liveness Rule 1

$$L_{out}(x, p) = \bigvee \{ L_{in}(x, s) \mid s \text{ a successor of } p \}$$

4/28/09

Prof. Hilfinger CS164 Lecture 27

49

Liveness Rule 2

$$L_{in}(x, s) = \text{true} \text{ if } s \text{ refers to } x \text{ on the rhs}$$

4/28/09

Prof. Hilfinger CS164 Lecture 27

50

Liveness Rule 3

$$L_{in}(x, x := e) = \text{false} \text{ if } e \text{ does not refer to } x$$

4/28/09

Prof. Hilfinger CS164 Lecture 27

51

Liveness Rule 4

$$L_{in}(x, s) = L_{out}(x, s) \text{ if } s \text{ does not refer to } x$$

4/28/09

Prof. Hilfinger CS164 Lecture 27

52

Algorithm

1. Let all $L_{in}(\dots) = \text{false}$ initially
2. Repeat until all statements s satisfy rules 1-4
 Pick s where one of 1-4 does not hold and update using the appropriate rule

4/28/09

Prof. Hilfinger CS164 Lecture 27

53

Another Example

4/28/09

Prof. Hilfinger CS164 Lecture 27

54

Termination

- A value can change from *false* to *true*, but not the other way around
- Each value can change only once, so termination is guaranteed
- Once the analysis is computed, it is simple to eliminate dead code

4/28/09

Prof. Hilfinger CS164 Lecture 27

55

SSA and Global Analysis

- For local optimizations, the single static assignment (SSA) form was useful.
- But how can it work with a full CFG?
 - E.g., how do we avoid two assignments to the temporary holding *x* after this conditional?

```
if a>b:
    x = a
else:
    x = b
# where is x at this point?
```

4/28/09

Prof. Hilfinger CS164 Lecture 27

56

A Small Kludge: ϕ "functions"

- For the preceding example, we get a CFG like this:

4/28/09

Prof. Hilfinger CS164 Lecture 27

57

ϕ "functions"

- An artificial device to allow SSA notation in CFGs.
- In a basic block, each variable is associated with *one* definition,
- ϕ -functions in effect associate each variable with a *set* of possible definitions.
- In general, one tries to introduce them in strategic places so as to minimize total number.
- Although this device increases number of assignments in IL, register allocation can remove many by assigning related IL registers to the same real register.

4/28/09

Prof. Hilfinger CS164 Lecture 27

58

Common Subexpression Elimination (CSE)

- Easy to tell (conservatively) if two IL assignments compute the same value: just see if they have the same right-hand side.
- Thanks to SSA, same variables indicate same values.

4/28/09

Prof. Hilfinger CS164 Lecture 27

59

Forward vs. Backward Analysis

We've seen two kinds of analysis:

Constant propagation is a *forwards* analysis: information is pushed from inputs to outputs

Liveness is a *backwards* analysis: information is pushed from outputs back towards inputs

4/28/09

Prof. Hilfinger CS164 Lecture 27

60

Analysis

- There are many other global flow analyses
- Most can be classified as either forward or backward
- Most also follow the methodology of local rules relating information between adjacent program points
