| Translating from AST to Stack Machine  | Virtual Register Machines and Three-Address Code  |  |
| <ul> <li>A simple recursive pattern usually serves for expressions.</li> <li>At the top level, our trees might have an expression-code method:<br/>class AST {</li> </ul>  | <ul> <li>Another common kind of virtual machine has an infinite supply of<br/>registers, each capable of holding a scalar value or address, in addi-<br/>tion to ordinary memory.</li> </ul>  |  |
| <pre> /** Generate code for me, leaving my value on the stack. */</pre>  | <ul> <li>A common IL in this case is some form of three-address code, so<br/>called because the typical "working" instruction has the form</li> </ul>   |  |
| <pre>virtual void cgen (VM* machine); }</pre>  | $target \mathrel{\mathop:}= operand_1 \oplus operand_2$   |  |
| <ul> <li>Implementations of cgen then obey this general comment, and each<br/>assumes that its children will as well. E.g.,</li> </ul>   | where there are two source "addresses," one destination "address" and an operation $(\oplus)$ .   |  |
| <pre>class BinopNode : public AST {      void cgen (VM* machine) {         getRight ()-&gt;cgen (machine);         getLeft ()-&gt;cgen (machine);         machine-&gt;emitInst (translateToInst (getOp ()));     } } We assume here a VM is some abstraction of the virtual machine union production and for the virtual machine</pre> | <ul> <li>Often, we require that the operands in the full three-address form<br/>denote (virtual) registers or immediate (literal) values.</li> </ul>  |  |
| we're producing code for. emitInst adds machine instructions to the program, and translateToInst converts, e.g., a '+' to add.   |   |  |
| Last modified: Wed Apr 7 19:37:26 2010 C5164: Lecture #21 7  | Last modified: Wed Apr 7 19:37:26 2010 C5164: Lecture #21 8   |  |

### Three-Address Code, continued

## A Larger Example

• Consider a small language with integers and integer operations:

```
P:
      D ";" P | D
D:
      "def" id(ARGS) "=" E;
ARGS: id "," ARGS | id
E:
      int | id | "if" E1 "=" E2 "then" E3 "else" E4 "fi"
          | E1 "+" E2 | E1 "-" E2 | id "(" E1,...,En ")"
```

- The first function definition f is the "main" routine
- Running the program on input i means computing f(i)
- Assume a project-2-like AST.
- Let's continue implementing cgen ('+' and '-' already done).

## Simple Cases: Literals and Sequences

Translating from AST into Three-Address Code

```
Conversion of D ";" P:
  class StmtListNode : public AST {
     Operand* cgen (VM* machine) {
        for (int i = 0; i < arity (); i += 1)
           get (i)->cgen (machine);
     }
     return Operand::NoneOperand;
  }
  class IntLiteralNode : public AST {
     Operand* cgen (VM* machine) {
         return machine->immediateOperand (intTokenValue ());
     }
  }
```

• NoneOperand is an Operand that contains None.

### Identifiers

```
class IdNode : public AST {
                                                                                              class CallNode : public AST {
     . . .
                                                                                                 . . .
     Operand* cgen (VM* machine) {
                                                                                                 Operand* cgen (VM* machine) {
        Operand result = machine->allocateRegister ();
                                                                                                    AST* args = getArgList ();
        machine->emitInst (MOVE, result, getDecl()->getMyLocation (machine));
                                                                                                    for (int i = args->arity ()-1; i >= 0; i -= 1)
        return result;
                                                                                                        machine->emitInst (PARAM, args.get (i)->cgen (machine));
     }
                                                                                                    Operand* callable = getCallable ()->cgen (machine);
  }
                                                                                                    machine->emitInst (CALL, callable, args->arity ());
                                                                                                    return Operand::ReturnOperand;
 • That is, we assume that the declaration object holding information
                                                                                                 }
   about this occurrence of the identifier contains its location.
                                                                                              7
                                                                                             • ReturnOperand is abstract location where functions return their
                                                                                               value.
                                                            CS164: Lecture #21 13
                                                                                                                                                        CS164: Lecture #21 14

        Label* doneLabel = machine->newLabel ();
                                                                                                    machine->emitInst (MOVE, Operand::ReturnOperand, result);
        machine->emitInst (IFNE, left, right, elseLabel);
                                                                                                    machine->emitFunctionEpilogue ();
        Operand* result = machine->allocateRegister ();
                                                                                                    return Operand::NoneOperand;
        machine->emitInst (MOVE, result, getThenPart ()->cgen (machine));
                                                                                                 }
        machine->emitInst (GOTO, doneLabel);
                                                                                              }
        machine->placeLabel (elseLabel);

    Where function prologues and epilogues are standard code sequences

        machine->emitInst (MOVE, result, getElsePart ()->cgen (machine));
                                                                                              for entering and leaving functions, setting frame pointers, etc.
        machine->placeLabel (doneLabel);
        return result;
     }
  }
 • newLabel creates a new, undefined assembler instruction label.
 • placeLabel inserts a definition of the label in the code.
```

Calls

# A Sample Translation

Program for computing the Fibonacci numbers:

def fib(x) = if x = 1 then 0 else if x = 2 then 1 else fib(x - 1) + fib(x - 2)

#### Possible code generated:

#### f: function prologue

| r1 := x                 | L3: r5 := x       |
|-------------------------|-------------------|
| if r1 != 1 then goto L1 | r6 := r5 - 1      |
| r2 := 0                 | param r6          |
| goto L2                 | call fib, 1       |
| L1: r3 := x             | r7 := rret        |
