### Lecture 7: General and Bottom-Up Parsing

#### Administrivia

- Homework 4 now out. It includes a component on Project #1, which you must do as a team.
- If you don't have a team, I'll assign one today. At the moment, I know of only one person without a team.
- There are a number of people who have a team, but who have not turned in one or more homeworks—not a good idea! These are easy points, and you must avoid falling behind.

#### A Little Notation

Here and in lectures to follow, we'll often have to refer to general productions or derivations. In these, we'll use various alphabets to mean various things:

- Capital roman letters are nonterminals (A, B, ...).
- Lower-case roman letters are terminals (or tokens, characters, etc.)
- Lower-case greek letters are sequences of zero or more terminal and nonterminal symbols, such as appear in sentential forms or on the right sides of productions  $(\alpha, \beta, \ldots)$ .
- Subscripts on lower-case greek letters indicate individual symbols within them, so  $\alpha = \alpha_1 \alpha_n \dots \alpha_n$  and each  $\alpha_i$  is a single terminal or nonterminal

#### For example,

- $A: \alpha$  might describe the production e: e '+' t,
- $B \Rightarrow \alpha A \gamma \Rightarrow \alpha \beta \gamma$  might describe the derivation steps e  $\Rightarrow$ e '+' t  $\Rightarrow$ e '+' ID ( $\alpha$  is e '+'; A is t; B is e; and  $\gamma$  is empty.)

### Fixing Recursive Descent

Can formulate top-down parsing analogously to NFAs.

```
parse (A, S): """Assuming A is a nonterminal and S = c_1c_2\dots c_n is a string, return integer k such that A can derive the prefix string c_1\dots c_k of S.""" Choose production 'A: \alpha_1\alpha_2\cdots\alpha_m' for A (nondeterministically) k=0 for x in \alpha_1,\ \alpha_2,\ \cdots,\ \alpha_m: if x is a terminal: if x==c_{k+1}: k+=1 else: GIVE UP else: k+= parse (x,\ c_{k+1}\cdots c_n)
```

- Assume that the grammar contains one production for the start symbol: p:  $\gamma$   $\dashv$ .
- We'll say that a call to parse returns a value if some set of choices for productions (the blue step) would return a value (just like NFA).
- Then if parse(p, S) returns a value, S must be in the language.

Consider parsing S="ID\*ID→" with a grammar from last time:

```
p : e '⊢'
e : t
| e '/' t
 | e '*' t
t : ID
```

Consider parsing S="ID\*ID→" with a grammar from last time:

```
p : e' \dashv A failing path through the program:
  e:t
                    parse(p, S):
    | e '/' t
                       Choose p : e '⊢':
    l e '*' t
                         parse(e, S):
  t.: ID
                             Choose e : t:
                                parse(t, S):
                                    choose t : ID:
                                       check S[1] == ID; OK, so k_3 += 1;
                                       return 1 (= k_3; added to k_2)
k_i means "the
                                return 1 (and add to k_1)
variable k in the
                         Check S[2] == S[k_1+1] == '-|': GIVE UP (S[2] == '*')
call to parse that
is nested i deep."
Outermost k is
```

 $k_1$ .

Consider parsing S="ID\*ID→" with a grammar from last time:

```
A successful path through the program:
  p : e '⊢'
  e:t
                     parse(p, S):
                        Choose p : e '⊢':
    | e '/' t
                           parse(e, S):
    l e '*' t
                               Choose e : e '*' t:
  t.: ID
                                  parse(e, S):
                                      choose e : t:
                                         parse(t, S):
                                            choose t : ID:
                                               check S[1] == ID; OK, so return 1
k_i means "the
                                         return 1 (so k_2 += 1)
variable k in the
                                  check S[k_2] == '*'; OK, k_2 += 1
call to parse that
                                  parse(t, S_3): # S_3 == "ID \dashv"
is nested i deep."
                                      choose t : ID:
Outermost k is
                                         check S_3[k_3+1] == S_3[1] == ID; OK
                                         k_3+=1; return 1 (so k_2 += 1)
k_1. Likewise for
                                      return 3
                           Check S[k_1+1] == S[4] == '-1': OK
```

 $k_1$  +=1; return 4

S.

### Making a Deterministic Algorithm

- If we had an infinite supply of processors, could just spawn new ones at each "Choose" line.
- Some would give up, some loop forever, but on correct programs, at least one processor would get through.
- To do this for real (say with one processor), need to keep track of all possibilities systematically.
- This is the idea behind Earley's algorithm:
  - Handles any context-free grammar.
  - Finds all parses of any string.
  - Runs in  $O(N^3)$  time for ambiguous grammars,  $O(N^2)$  time for "nondeterministic grammars", or O(N) time for deterministic grammars (such as accepted by Bison).

## Earley's Algorithm: I

 First, reformulate to use recursion instead of looping. Assume the string  $S = c_1 \cdots c_n$  is fixed.

```
parse (A: \alpha \bullet \beta, s, k):
    """Assumes A: \alpha\beta is a production in the grammar,
       0 <= s <= k <= n, and lpha can produce the string c_{s+1} \cdots c_k.
       Returns integer j such that \beta can produce c_{k+1} \cdots c_i.""
    if \beta is empty:
       return k
   Assume \beta has the form x\delta
    if x is a terminal:
        if x == c_{k+1}:
             return parse(A: \alpha x \bullet \delta, s, k+1)
       else:
             GIVE UP
    else:
       Choose production 'x: \kappa' for x (nondeterministically)
        j = parse(x: \bullet \kappa, k, k)
       return parse (A: \alpha x \bullet \delta, s, j)
```

 Now do all possible choices that result in such a way as to avoid redundant work ("nondeterministic memoization").

#### Chart Parsing

- Idea is to build up a table (known as a chart) of all calls to parse that have been made.
- Only one entry in chart for each distinct triple of arguments (A:  $\alpha \bullet \beta$ , s, k).
- ullet We'll organize table in columns numbered by the k parameter, so that column k represents all calls that are looking at  $c_{k+1}$  in the input.
- Each column contains entries with the other two parameters: [A:  $\alpha \bullet \beta$ , s], which is called an item.
- The columns, therefore, are item sets.

Grammar

Input String

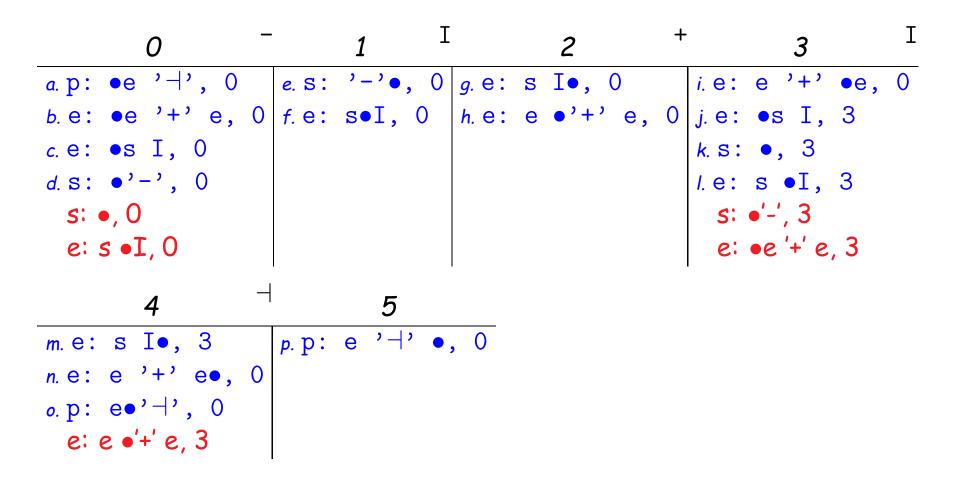

- I + I ⊢

**Chart**. Headings are values of k and  $c_{k+1}$  (raised symbols).

|              | 0         | _        | 1       | •<br>•  | 2       | +            | 3               | I |
|--------------|-----------|----------|---------|---------|---------|--------------|-----------------|---|
|              | •e '⊢', 0 |          |         |         |         |              |                 |   |
| <i>b.</i> e: | •e '+' e, | 0 f.e:   | s•I, O  | h. e: e | •'+' e, |              |                 |   |
| <i>c.</i> e: | •s I, 0   |          |         |         |         | k. s:        | •, 3<br>s •I, 3 |   |
| d. S:        | • '-', O  |          |         |         |         | <i>I.</i> e: | s •I, 3         | 3 |
|              | 4         | $\dashv$ | 5       |         |         | ·            |                 |   |
| m. e:        | s I•, 3   | p. p:    | e '⊢' • | , 0     |         |              |                 |   |
| n. e:        | e '+' e•, | 0        |         |         |         |              |                 |   |
| o. p:        | e•'⊢', 0  |          |         |         |         |              |                 |   |

### Example, completed

 Last slide showed only those items that survive and get used. Algorithm actually computes dead ends as well (unlettered, in red).

# Adding Semantic Actions

- Pretty much like recursive descent. The call parse (A:  $\alpha \bullet \beta$ , s, k) can return, in addition to j, the semantic value of the A that matches characters  $c_{s+1} \cdots c_i$ .
- This value is actually computed during calls of the form parse(A:  $\alpha'$ •, s, k) (i.e., where the  $\beta$  part is empty).
- Assume that we have attached these values to the nonterminals in  $\alpha$ , so that they are available when computing the value for A.

### **Ambiguity**

- Ambiguity only important here when computing semantic actions.
- Rather than being satisfied with a single path through the chart, we look at all paths.
- And we attach the set of possible results of parse(Y:  $\bullet \kappa$ , s, k) to the nonterminal Y in the algorithm.
