# Q1. [13 pts] Search Party

(a) [3 pts] First consider **general search problems**, which of the following are true?

- Code that implements A\* tree search can be used to run UCS.
- A\* tree search is optimal with any heuristic function.
- A\* tree search is complete with any heuristic function.
- A\* graph search is guaranteed to expand no more nodes than DFS.
- The max of two admissible heuristics is always admissible.
- A heuristic that always evaluates to  $h(s) = 1$  for non-goal search nodes  $s$  is always admissible.

Now consider the following real-world scenario. Annie is throwing a party tonight, but she only has a couple hours to get ready. Luckily, she was recently gifted 4 one-armed robots! She will use them to rearrange her room for the guests while she is busy getting everything else ready. Here are the specifications:

- Her room is modeled as a  $W$ -by- $L$ -by- $H$  3D grid in which there are  $N$  objects (which could be anywhere in the grid to start with) that need rearrangement.
- Each object occupies one grid cell, and no two objects can be in the same grid cell. Do not consider any part of the robot an “object.”
- At each time-step, one robot may take an action  $\in \{\text{move gripper to legal grid cell, close gripper, open gripper}\}$ . Moving the gripper does not change whether the gripper was closed/open.
- A robot can move an object by
  1. Moving an open gripper into the object’s grid cell
  2. Closing the gripper to grasp the object
  3. Moving to desired location
  4. Opening the gripper to release the object in-hand.
- The robots do not have unlimited range. The arm can move to any point *within* the room that is strictly less than  $R$  grid cells from its base per direction along each axis. Explicitly, if  $R = 2$  and a robot’s base is at  $(0,0,0)$ , the robot cannot reach  $(0,0,2)$  but can reach  $(1,1,1)$ . Assume  $R < W, L, H$ .

- (b) [4 pts] Annie stations one robot's stationary base at each of the 4 *corners* of the room (see figure for example of this with 3 objects). Thankfully, she knows where each of the  $N$  objects in the room should be and uses that to define the robots' goal. Complete the following expression such that it evaluates to the size of the minimal state space. Please approximate permutations as follows:  $X$  permute  $Y \approx X^Y$ . You may use scalars and the variables:  $W$ ,  $L$ ,  $H$ ,  $R$ , and  $N$  in your answers.

$$2^{(a)} \cdot N^{(b)} \cdot R^{(c)} \cdot W^{(d)} \cdot L^{(e)} \cdot H^{(f)}$$

(a):	<input type="text"/>	(b):	<input type="text"/>	(c):	<input type="text"/>
(d):	<input type="text"/>	(e):	<input type="text"/>	(f):	<input type="text"/>

- (c) Each of the following describes a modification to the scenario previously described and depicted in the figure. **Consider each modification independently (that is, the modifications introduced in (i) are *not* present in (ii)).** For each scenario, give the size of the new minimal state space. **Please use the symbol  $X$  as a proxy for the correct answer to (b) in your answers.**

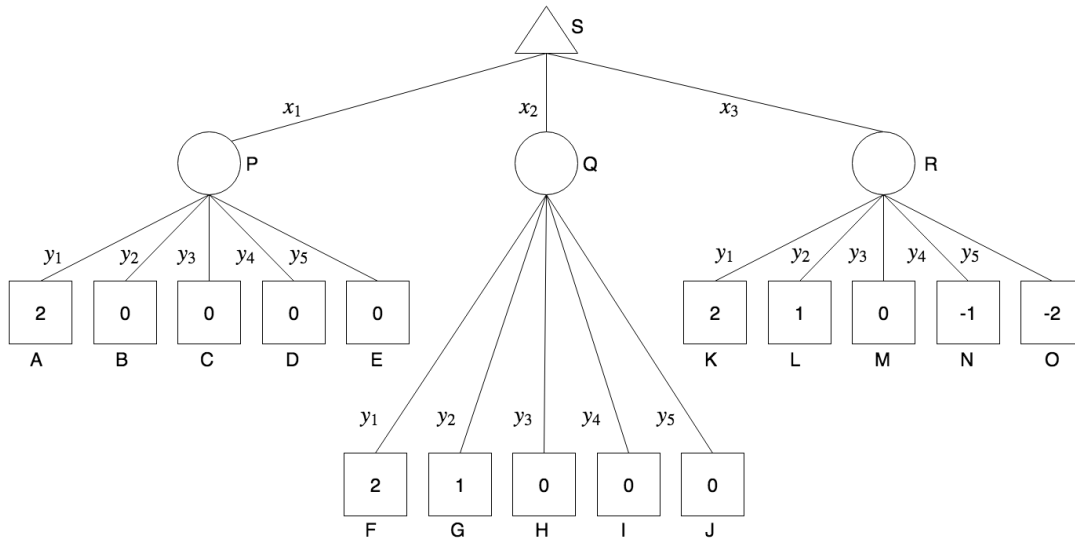

- (i) [3 pts] The robots are given wheels, so each base is able to slide along the floor (they still cant jump) from their original corners. That is, at each time-step, a robot has a new action that allows them to move its (once stationary) base arbitrarily far across the floor. When the robot slides its base, the relative arm position and status of the gripper remain the same.

- (ii) [3 pts] *One* robot is defective and can move for a maximum of  $T$  timesteps before it must rest for at least  $S$  timesteps. You may use  $S$  or  $T$  in your expression.

## Q2. [15 pts] Bike Bidding Battle

Alyssa P. Hacker and Ben Bitdiddle are bidding in an auction at Stanley University for a bike. Alyssa will either bid  $x_1$ ,  $x_2$ , or  $x_3$  for the bike. She knows that Ben will bid  $y_1, y_2, y_3, y_4$ , or  $y_5$ , but she does not know which. All bids are nonnegative.

- (a) Alyssa wants to maximize her payoff given by the expectimax tree below. The leaf nodes show Alyssa's payoff. The nodes are labeled by letters, and the edges are labeled by the bid values  $x_i$  and  $y_j$ . The maximization node S represents Alyssa, and the branches below it represent each of her bids:  $x_1, x_2, x_3$ . The chance nodes P, Q, R represent Ben, and the branches below them represent each of his bids:  $y_1, y_2, y_3, y_4, y_5$ .

- (i) [2 pts] Suppose that Alyssa believes that Ben would bid any bid with equal probability. What are the values of the chance (circle) and maximization (triangle) nodes?

1. Node P \_\_\_\_\_
2. Node Q \_\_\_\_\_
3. Node R \_\_\_\_\_
4. Node S \_\_\_\_\_

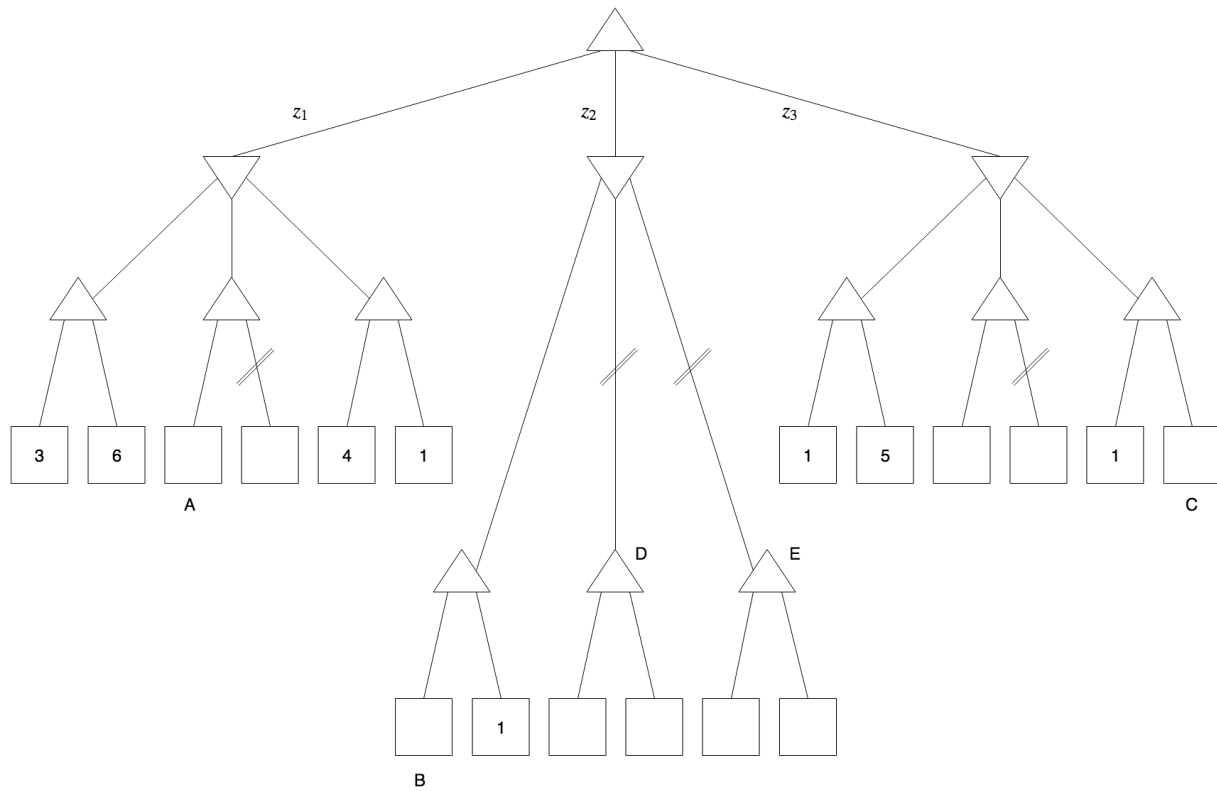

- (ii) [1 pt] Based on the information from the above tree, how much should Alyssa bid for the bike?

$x_1$         $x_2$         $x_3$

- (b) [3 pts] Alyssa does expectimax search by visiting child nodes from left to right. Ordinarily expectimax trees cannot be pruned without some additional information about the tree. Suppose, however, that Alyssa knows that the leaf nodes are ordered such that payoffs are non-increasing from left to right (the leaf nodes of the above diagram is an example of this ordering). Recall that if node  $X$  is a child of a maximizer node, a child of node  $X$  may be pruned if we know that the value of node  $X$  will never be  $>$  some threshold (in other words, it is  $\leq$  that threshold). Given this information, if it is possible to prune any branches from the tree, mark them below. Otherwise, mark "None of the above."

A    B    C    D    E    F    G    H  
 I    J    K    L    M    N    O    None of the above

(c) [4 pts] Unrelated to parts (a) and (b), consider the minimax tree below. whose leaves represent payoffs for the maximizer. The crossed out edges show the edges that are pruned when doing naive alpha-beta pruning visiting children nodes from left to right. Assume that we prune on equalities (as in, we prune the rest of the children if the current child is  $\leq \alpha$  (if the parent is a minimizer) or  $\geq \beta$  (if the parent is a maximizer)).

Fill in the inequality expressions for the values of the labeled nodes A and B. Write  $\infty$  and  $-\infty$  if there is no upper or lower bound, respectively.

1.   $\leq A \leq$

2.   $\leq B \leq$

(d) [1 pt] Suppose node B took on the largest value it could possibly take on and still be consistent with the pruning scheme above. After running the pruning algorithm, we find that the values of the left and center subtrees have the same minimax value, both 1 greater than the minimax value of the right subtree. Based on this information, what is the numerical value of node C?

- 1  
 2  
 3  
 4  
 5  
 6  
 7  
 8  
 9  
 10

(e) [4 pts] For which values of nodes D and E would choosing to take action  $z_2$  be *guaranteed* to yield the same payoff as action  $z_1$ ? Write  $\infty$  and  $-\infty$  if there is no upper or lower bound, respectively (this would correspond to the case where nodes D and E can be any value).

1.   $\leq D \leq$

2.   $\leq E \leq$

### Q3. [17 pts] How do you Value It(eration)?

(a) Fill out the following True/False questions.

- (i) [1 pt]  True  False: Let  $A$  be the set of all actions and  $S$  the set of states for some MDP. Assuming that  $|A| \ll |S|$ , one iteration of value iteration is generally faster than one iteration of policy iteration that solves a linear system during policy evaluation.
  
- (ii) [1 pt]  True  False: For any MDP, changing the discount factor does not affect the optimal policy for the MDP.

The following problem will take place in various instances of a grid world MDP. Shaded cells represent walls. In all states, the agent has available actions  $\uparrow, \downarrow, \leftarrow, \rightarrow$ . Performing an action that would transition to an invalid state (outside the grid or into a wall) results in the agent remaining in its original state. In states with an arrow coming out, the agent has an *additional* action *EXIT*. In the event that the *EXIT* action is taken, the agent receives the labeled reward and ends the game in the terminal state  $T$ . Unless otherwise stated, all other transitions receive no reward, and all transitions are deterministic.

For all parts of the problem, assume that value iteration begins with all states initialized to zero, i.e.,  $V_0(s) = 0 \forall s$ . **Let the discount factor be  $\gamma = \frac{1}{2}$  for all following parts.**

(b) Suppose that we are performing value iteration on the grid world MDP below.

(i) [2 pts] Fill in the optimal values for A and B in the given boxes.

$V^*(A)$  :        $V^*(B)$  :

(ii) [2 pts] After how many iterations  $k$  will we have  $V_k(s) = V^*(s)$  for all states  $s$ ? If it never occurs, write "never". Write your answer in the given box.

(iii) [3 pts] Suppose that we wanted to re-design the reward function. For which of the following new reward functions would the optimal policy **remain unchanged**? Let  $R(s, a, s')$  be the original reward function.

- $R_1(s, a, s') = 10R(s, a, s')$
- $R_2(s, a, s') = 1 + R(s, a, s')$
- $R_3(s, a, s') = R(s, a, s')^2$
- $R_4(s, a, s') = -1$
- None

(c) For the following problem, we add a new state in which we can take the *EXIT* action with a reward of  $+x$ .

(i) [3 pts] For what values of  $x$  is it *guaranteed* that our optimal policy  $\pi^*$  has  $\pi^*(C) = \leftarrow$ ? Write  $\infty$  and  $-\infty$  if there is no upper or lower bound, respectively. Write the upper and lower bounds in each respective box.

$< x <$

(ii) [3 pts] For what values of  $x$  does value iteration take the **minimum** number of iterations  $k$  to converge to  $V^*$  for all states? Write  $\infty$  and  $-\infty$  if there is no upper or lower bound, respectively. Write the upper and lower bounds in each respective box.

$\leq x \leq$

(iii) [2 pts] Fill the box with value  $k$ , the **minimum** number of iterations until  $V_k$  has converged to  $V^*$  for all states.

## Q4. [12 pts] Q-uagmire

Consider an unknown MDP with three states ( $A$ ,  $B$  and  $C$ ) and two actions ( $\leftarrow$  and  $\rightarrow$ ). Suppose the agent chooses actions according to some policy  $\pi$  in the unknown MDP, collecting a dataset consisting of samples  $(s, a, s', r)$  representing taking action  $a$  in state  $s$  resulting in a transition to state  $s'$  and a reward of  $r$ .

$s$	$a$	$s'$	$r$
$A$	$\rightarrow$	$B$	2
$C$	$\leftarrow$	$B$	2
$B$	$\rightarrow$	$C$	-2
$A$	$\rightarrow$	$B$	4

You may assume a discount factor of  $\gamma = 1$ .

(a) Recall the update function of  $Q$ -learning is:

$$Q(s_t, a_t) \leftarrow (1 - \alpha)Q(s_t, a_t) + \alpha \left( r_t + \gamma \max_{a'} Q(s_{t+1}, a') \right)$$

Assume that all  $Q$ -values are initialized to 0, and use a learning rate of  $\alpha = \frac{1}{2}$ .

(i) [3 pts] Run  $Q$ -learning on the above experience table and fill in the following  $Q$ -values:

$$Q(A, \rightarrow) = \underline{\hspace{2cm}} \quad Q(B, \rightarrow) = \underline{\hspace{2cm}}$$

-                      -  
-                      -  
-                      -  
-                      -

(ii) [2 pts] After running  $Q$ -learning and producing the above  $Q$ -values, you construct a policy  $\pi_Q$  that maximizes the  $Q$ -value in a given state:

$$\pi_Q(s) = \arg \max_a Q(s, a).$$

What are the actions chosen by the policy in states  $A$  and  $B$ ?

$\pi_Q(A)$  is equal to:

- $\pi_Q(A) = \leftarrow$ .  
  $\pi_Q(A) = \rightarrow$ .  
  $\pi_Q(A) = \text{Undefined}$ .

$\pi_Q(B)$  is equal to:

- $\pi_Q(B) = \leftarrow$ .  
  $\pi_Q(B) = \rightarrow$ .  
  $\pi_Q(B) = \text{Undefined}$ .

(b) [3 pts] Use the empirical frequency count model-based reinforcement learning method described in lectures to estimate the transition function  $\hat{T}(s, a, s')$  and reward function  $\hat{R}(s, a, s')$ . (Do not use pseudocounts; if a transition is not observed, it has a count of 0.)

Write down the following quantities. You may write N/A for undefined quantities.

$$\hat{T}(A, \rightarrow, B) = \underline{\hspace{2cm}} \quad \hat{R}(A, \rightarrow, B) = \underline{\hspace{2cm}}$$

$$\hat{T}(B, \rightarrow, A) = \underline{\hspace{2cm}} \quad \hat{R}(B, \rightarrow, A) = \underline{\hspace{2cm}}$$

$$\hat{T}(B, \leftarrow, A) = \underline{\hspace{2cm}} \quad \hat{R}(B, \leftarrow, A) = \underline{\hspace{2cm}}$$

(c) This question considers properties of reinforcement learning algorithms for *arbitrary* discrete MDPs; you do not need to refer to the MDP considered in the previous parts.

(i) [2 pts] Which of the following methods, at convergence, provide enough information to obtain an optimal policy? (Assume adequate exploration.)

- Model-based learning of  $T(s, a, s')$  and  $R(s, a, s')$ .
- Direct Evaluation to estimate  $V(s)$ .
- Temporal Difference learning to estimate  $V(s)$ .
- Q-Learning to estimate  $Q(s, a)$ .

(ii) [2 pts] In the limit of infinite timesteps, under which of the following exploration policies is Q-learning guaranteed to converge to the optimal Q-values for all state? (You may assume the learning rate  $\alpha$  is chosen appropriately, and that the MDP is ergodic: i.e., every state is reachable from every other state with non-zero probability.)

- A fixed policy taking actions uniformly at random.
- A greedy policy.
- An  $\epsilon$ -greedy policy
- A fixed optimal policy.

## Q5. [18 pts] Dudoku

Here we introduce Dudokus, a type of CSP problem. A Dudoku consists of variables and summation constraints. The circles indicate variables that can take integer values in a specified range and the boxes indicate summation constraints, which specify that the variables connected to the constraint need to add up to the number given in the box.

- (a) Let's begin with linear Dudokus, where the variables can be arranged in a linear chain with constraints between adjacent pairs. For example, in the linear Dudoku below, variables  $A$ ,  $B$ , and  $C$  need values assigned to them in the set  $\{1, 2, 3\}$  such that  $A + B = 4$  and  $B + C = 3$ .

- (i) [2 pts] How many solutions does this Dudoku have?

0     
  1     
  2     
  3     
  more than 3

- (ii) [1 pt] Consider the general case of a linear Dudoku with  $n$  variables  $X_1, \dots, X_n$ , each taking a value in  $\{1, \dots, d\}$ . What is the complexity for solving such a Dudoku using the generic tree-CSP algorithm?

$\mathcal{O}(nd^3)$      
   $\mathcal{O}(n^2d^2)$      
   $\mathcal{O}(nd^2)$      
   $\mathcal{O}(d^n)$

- (iii) [2 pts] One proposal for solving linear Dudokus is as follows: for each possible value  $i$  of the first variable  $X_1$  in the chain, instantiate  $X_1$  with that value and then run generic arc consistency beginning with the pair  $(X_2, X_1)$  until termination; keep going until a solution is found or there are no more values to try for  $X_1$ . Which of the following are true?

- This will correctly detect any unsolvable Dudoku.  
 This will always solve any solvable Dudoku.  
 This will sometimes terminate without finding a solution when one exists.  
 The runtime is  $\mathcal{O}(nd^3)$ .

- (iv) [2 pts] Binary Dudoku constraints are *one-to-one*, meaning that if one variable in a binary constraint has a known value, there is only one possible value for the other variable. Suppose we modify arc consistency to take advantage of one-to-one constraints instead of checking all possible pairs of values when checking a constraint. Now the runtime of the algorithm in the previous part becomes:

$\mathcal{O}(nd)$      
   $\mathcal{O}(nd^3)$      
   $\mathcal{O}(n^2d^2)$      
   $\mathcal{O}(nd^2)$

- (b) [4 pts] Branching Dudokus

Example A

Example B

A branching Dudoku is one in which multiple linear chains are joined together. Chains can be joined at a summation node, as in example A above, or at a variable, as in example B above. Recall that a cutset is a set of nodes that can be removed from a graph to ensure some desired property. Which of the following are true?

- Dudoku A is a binary CSP.
- Dudoku B is a binary CSP.
- Dudoku A is a tree-structured CSP.
- Dudoku B is a tree-structured CSP.
- If variables  $B$ ,  $D$ , and  $F$  are merged into a single megavariabale, Dudoku A will be a tree-structured CSP.
- If variables  $A$  and  $E$  are merged into a single megavariabale, Dudoku B will be a tree-structured CSP.
- The minimum cutset that turns Dudoku A into a set of disjoint linear Dudokus contains 3 variables.
- The minimum cutset that turns Dudoku B into a set of disjoint linear Dudokus contains 1 variable.

(c) Circular Dudokus

Example 1

Example 2

- (i) [2 pts] The figure above shows two examples of circular Dudokus. If we apply cutset conditioning with a minimal cutset and a tree-CSP solver, what is the runtime for a circular Dudoku with  $n$  variables and domain size  $d$ ?

$\mathcal{O}(d^{n-1})$         $\mathcal{O}(n^2d^2)$         $\mathcal{O}(nd)$         $\mathcal{O}(nd^3)$

(ii) [2 pts] Suppose that the variables in the circular Dudokus in the figure are assigned values such that all the constraints are satisfied. Assume also that the variable domains are integers in  $[-\infty, \infty]$ . Now consider what happens if we add 1 to the value of variable  $A$  in each Dudoku and then re-solve with  $A$  fixed at its new value. Which of the following are true?

- Dudoku 1 now has no solution.  
 Dudoku 2 now has no solution.

(iii) [4 pts] What can you conclude about the number of solutions to a circular Dudoku with  $n$  variables?

## Q6. [13 pts] In What Worlds?

(a) We wish to come up with hypotheses that entail the following sentences:

- $S_1: X_1 \wedge X_2 \implies Y$
- $S_2: \neg X_1 \vee X_2 \implies Y$

In this problem, we want to come up with a hypothesis  $H$  such that  $H \models S_1 \wedge H \models S_2$ .

(i) [3 pts] Assume we have the hypothesis  $H: Y \iff X_1 \vee X_2$ .

Does  $H$  entail  $S_1$ ?     Yes     No

Does  $H$  entail  $S_2$ ?     Yes     No

(ii) [3 pts] Pretend that we have obtained a magical solver,  $SAT(s)$  which takes in a sentence  $s$  and returns *true* if  $s$  is satisfiable and *false* otherwise. We wish to use this solver to determine whether a hypothesis  $H'$  entails the two sentences  $S_1$  and  $S_2$ . Mark all of the following expressions that correctly return *true* if and only if  $H' \models S_1 \wedge H' \models S_2$ . If none of the expressions are correct, select “None of the above”.

$SAT(H' \wedge \neg(S_1 \wedge S_2))$       $SAT(\neg H' \vee (S_1 \wedge S_2))$

$\neg SAT(H' \wedge \neg(S_1 \wedge S_2))$       $\neg SAT(\neg H' \vee (S_1 \wedge S_2))$

None of the above

Four people, Alex, Betty, Cathy, and Dan are going to a family gathering. They can bring dishes or games. They have the following predicates in their vocabulary:

- $Brought(p, i)$ : Person  $p$  brought a dish or game  $i$ .
- $Cooked(p, d)$ : Person  $p$  cooked dish  $d$ .
- $Played(p, g)$ : Person  $p$  played game  $g$ .

(b) Select which first-order logic sentences are syntactically correct translations for the following English sentences. You must use the syntax shown in class (eg.  $\forall, \exists, \wedge, \implies, \iff$ ). **Please select all that apply.**

(i) [2 pts] At least one dish cooked by Alex was brought by Betty.

- $\exists d Cooked(A, d) \wedge Brought(B, d)$   
  $[\exists d Cooked(A, d)] \wedge [\forall d' \wedge (d' = d) Brought(B, d')]$   
  $\neg[\forall d Cooked(A, d) \vee Brought(B, d)]$   
  $\exists d_1, d_2 Cooked(A, d_1) \wedge (d_2 = d_1) \wedge Brought(B, d_2)$

(ii) [2 pts] At least one game played by Cathy is only played by people who brought dishes.

- $\neg[\forall g Played(C, g) \vee [\exists p Played(p, g) \implies \forall d Brought(p, d)]]$   
  $\forall p \exists g Played(C, g) \wedge Played(p, g) \implies \exists d Brought(p, d)$   
  $\exists g Played(C, g) \implies \forall p \exists d Played(p, g) \wedge Brought(p, d)$   
  $\exists g Played(C, g) \wedge [\forall p Played(p, g) \implies \exists d, Brought(p, d)]$

(c) Assume we have the following sentence with variables  $A, B, C$ , and  $D$ , where each variable takes Boolean values:

$$S3: (A \vee B \vee \neg C) \wedge (A \vee \neg B \vee D) \wedge (\neg B \vee \neg D)$$

(i) [2 pts] For the above sentence  $S3$ , state how many worlds make the sentence true. [Hint: you can do this and the next part without constructing a truth table!]

(ii) [1 pt] Does  $S3 \models (A \wedge B \wedge D)$ ?

Yes

No

# Q7. [12 pts] Proba-Potpourri

(a) [3 pts]

Consider the Bayes' net shown above. In the box given below, write down an expression for  $P(A|B, C, D)$  in terms of conditional probability distributions  $P(B|A)$ ,  $P(C|A)$ ,  $P(A)$ . If it is not possible to write down such an expression, mark the circle next to "Not possible".

Not possible.

(b) [3 pts] Given the same Bayes' net as in part (a), write down an expression for  $P(D|A)$  in terms of conditional probability distributions  $P(D|B, C)$ ,  $P(B|A)$  and  $P(C|A)$ . If it is not possible to write down such an expression, mark the circle next to "Not possible".

Not possible.

(c) [3 pts] Consider the Bayes' net shown below

Write down an expression for  $P(B|C)$  in terms of conditional probability distributions  $P(B|A, D)$ ,  $P(C|A, D)$ . If it is not possible to write such an expression, mark the circle next to "Not possible".

Not possible.

(d) [3 pts] Consider the Bayes' net shown below

You have access to all the conditional probability tables associated with the Bayes net above except  $P(C|B)$ , and you would like to determine  $P(E|B)$  using this information. You are allowed to remove one edge from the given Bayes net. Select **all** possible single edges that you can remove in order to successfully compute  $P(E|B)$  from  $P(E|A, D)$ ,  $P(A|B)$ ,  $P(D|B, C)$  and  $P(B)$ . For examples, if you can remove the edge from B to C, or the edge from A to E, select 0 and 5. If there is no such single edge that you can remove, mark the circle next to "Not Possible".

0    1    2    3    4    5                       Not Possible
