

Q1. MDP

Pacman is using MDPs to maximize his expected utility. In each environment:

- Pacman has the standard actions {North, East, South, West} unless blocked by an outer wall
- There is a reward of 1 point when eating the dot (for example, in the grid below, $R(C, South, F) = 1$)
- The game ends when the dot is eaten

(a) Consider a the following grid where there is a single food pellet in the bottom right corner (F). The **discount** factor is 0.5. There is no living reward. The states are simply the grid locations.

A	B	C
D	E	F ○

(i) What is the optimal policy for each state?

State	$\pi(state)$
A	
B	
C	
D	
E	

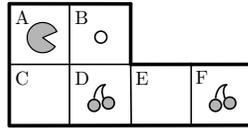

(ii) What is the optimal value for the state of being in the upper left corner (A)? Reminder: the discount factor is 0.5.

$V^*(A) =$

(iii) Using value iteration with the value of all states equal to zero at $k=0$, for which iteration k will $V_k(A) = V^*(A)$?

$k =$

- (b) Consider a new Pacman level that begins with cherries in locations D and F . Landing on a grid position with cherries is worth 5 points and then the cherries at that position disappear. There is still one dot, worth 1 point. The game still only ends when the dot is eaten.

- (i) With no discount ($\gamma = 1$) and a living reward of -1, perform one iteration of policy iteration in this level's state space, starting from the fixed policy below.

State	A	C	D, $F_{\text{Cherry}}=\text{true}$	D, $F_{\text{Cherry}}=\text{false}$	E, $F_{\text{Cherry}}=\text{true}$	E, $F_{\text{Cherry}}=\text{false}$	F
π_i	East	East	North	North	West	West	West
V^{π_i}							
π_{i+1}							

- (ii) With no discount ($\gamma = 1$), what is the range of living reward values such that Pacman eats exactly one cherry when starting at position A ?

Q2. Markov Decision Processes

Consider a simple MDP with two states, S_1 and S_2 , two actions, A and B , a discount factor γ of $1/2$, reward function R given by

$$R(s, a, s') = \begin{cases} 1 & \text{if } s' = S_1; \\ -1 & \text{if } s' = S_2; \end{cases}$$

and a transition function specified by the following table.

s	a	s'	$T(s, a, s')$
S_1	A	S_1	$1/2$
S_1	A	S_2	$1/2$
S_1	B	S_1	$2/3$
S_1	B	S_2	$1/3$
S_2	A	S_1	$1/2$
S_2	A	S_2	$1/2$
S_2	B	S_1	$1/3$
S_2	B	S_2	$2/3$

- (a) Perform a single iteration of value iteration, filling in the resultant Q-values and state values in the following tables. Use the specified initial value function V_0 , rather than starting from all zero state values. Only compute the entries not labeled “skip”.

s	a	$Q_1(s, a)$
S_1	A	
S_1	B	
S_2	A	skip
S_2	B	skip

s	$V_0(s)$	$V_1(s)$
S_1	2	
S_2	3	skip

- (b) Given an arbitrary MDP with state set S , transition function $T(s, a, s')$, discount factor γ , and reward function $R(s, a, s')$, and given a constant $\beta > 0$, consider a modified MDP (S, T, γ, R') with reward function $R'(s, a, s') = \beta \cdot R(s, a, s')$. Prove that the modified MDP (S, T, γ, R') has the same set of optimal policies as the original MDP (S, T, γ, R) .
- (c) Although in this class we have defined MDPs as having a reward function $R(s, a, s')$ that can depend on the initial state s and the action a in addition to the destination state s' , MDPs are sometimes defined as having a reward function $R(s')$ that depends only on the destination state s' . Given an arbitrary MDP with state set S , transition function $T(s, a, s')$, discount factor γ , and reward function $R(s, a, s')$ that *does depend* on the initial state s and the action a , define an *equivalent* MDP with state set S' , transition function $T'(s, a, s')$, discount factor γ' , and reward function $R'(s')$ that depends only on the destination state s' .

By *equivalent*, it is meant that there should be a one-to-one mapping between state-action sequences in the original MDP and state-action sequences in the modified MDP (with the same value). **You do not need to give a proof of the equivalence.**

States: $S' =$

Transition function: $T'(s, a, s') =$

Discount factor: $\gamma' =$

Reward function: $R'(s') =$

Q3. Direct Evaluation

Consider the grid-world given below and an agent who is trying to learn the optimal policy. Rewards are only awarded for taking the *Exit* action from one of the shaded states. Taking this action moves the agent to the Done state, and the MDP terminates. Assume $\gamma = 1$ and $\alpha = 0.5$ for all calculations. All equations need to explicitly mention γ and α if necessary.

- (a) The agent starts from the top left corner and you are given the following episodes from runs of the agent through this grid-world. Each line in an Episode is a tuple containing (s, a, s', r) .

Episode 1	Episode 2	Episode 3	Episode 4	Episode 5
(1,3), S, (1,2), 0	(1,3), S, (1,2), 0	(1,3), S, (1,2), 0	(1,3), S, (1,2), 0	(1,3), S, (1,2), 0
(1,2), E, (2,2), 0	(1,2), E, (2,2), 0	(1,2), E, (2,2), 0	(1,2), E, (2,2), 0	(1,2), E, (2,2), 0
(2,2), E, (3,2), 0	(2,2), S, (2,1), 0	(2,2), E, (3,2), 0	(2,2), E, (3,2), 0	(2,2), E, (3,2), 0
(3,2), N, (3,3), 0	(2,1), Exit, D, -100	(3,2), S, (3,1), 0	(3,2), N, (3,3), 0	(3,2), S, (3,1), 0
(3,3), Exit, D, +50		(3,1), Exit, D, +30	(3,3), Exit, D, +50	(3,1), Exit, D, +30

Fill in the following Q-values obtained from direct evaluation from the samples:

$$Q((3,2), N) = \underline{\hspace{2cm}} \qquad Q((3,2), S) = \underline{\hspace{2cm}} \qquad Q((2,2), E) = \underline{\hspace{2cm}}$$
