Midterm Review RL

Q1. RL

Pacman is in an unknown MDP where there are three states [A, B, C] and two actions [Stop, Go]. We are given the following samples generated from taking actions in the unknown MDP. For the following problems, assume $\gamma = 1$ and $\alpha = 0.5$.

(a) We run Q-learning on the following samples:

s	**a**	**s'**	**r**
A	Go	B	2
C	Stop	A	0
B	Stop	A	-2
B	Go	C	-6
C	Go	A	2
A	Go	A	-2

What are the estimates for the following Q-values as obtained by Q-learning? All Q-values are initialized to 0.

(i) $Q(C, Stop) =$ ______________________________

(ii) $Q(C, Go) =$ ______________________________

(b) For this next part, we will switch to a feature based representation. We will use two features:

- $f_1(s, a) = 1$
- $f_2(s, a) = \begin{cases} 1 & a = \text{Go} \\ -1 & a = \text{Stop} \end{cases}$

Starting from initial weights of 0, compute the updated weights after observing the following samples:

s	**a**	**s'**	**r**
A	Go	B	4
B	Stop	A	0

What are the weights after the first update? (using the first sample)

(i) $w_1 =$ ______________________________

(ii) $w_2 =$ ______________________________

What are the weights after the second update? (using the second sample)

(iii) $w_1 =$ ______________________________

(iv) $w_2 =$ ______________________________

Q2. Q-uagmire

Consider an unknown MDP with three states (A, B and C) and two actions ($\leftarrow$ and $\rightarrow$). Suppose the agent chooses actions according to some policy π in the unknown MDP, collecting a dataset consisting of samples (s, a, s', r) representing taking action a in state s resulting in a transition to state s' and a reward of r.

s	a	s'	r
A	$\rightarrow$	B	2
C	$\leftarrow$	B	2
B	$\rightarrow$	C	-2
A	$\rightarrow$	B	4

You may assume a discount factor of $\gamma = 1$.

(a) Recall the update function of Q-learning is:

$$Q(s_t, a_t) \leftarrow (1-\alpha)Q(s_t, a_t) + \alpha \left(r_t + \gamma \max_{a'} Q(s_{t+1}, a')\right)$$

Assume that all Q-values are initialized to 0, and use a learning rate of $\alpha = \frac{1}{2}$.

(i) Run Q-learning on the above experience table and fill in the following Q-values:

$Q(A, \rightarrow) =$ ______________________ $Q(B, \rightarrow) =$ ______________________

(ii) After running Q-learning and producing the above Q-values, you construct a policy π_Q that maximizes the Q-value in a given state:

$$\pi_Q(s) = \arg\max_a Q(s, a).$$

What are the actions chosen by the policy in states A and B?

$\pi_Q(A)$ is equal to:

- ○ $\pi_Q(A) = \leftarrow$.
- ○ $\pi_Q(A) = \rightarrow$.
- ○ $\pi_Q(A) =$ Undefined.

$\pi_Q(B)$ is equal to:

- ○ $\pi_Q(B) = \leftarrow$.
- ○ $\pi_Q(B) = \rightarrow$.
- ○ $\pi_Q(B) =$ Undefined.

(b) Use the empirical frequency count model-based reinforcement learning method described in lectures to estimate the transition function $\hat{T}(s, a, s')$ and reward function $\hat{R}(s, a, s')$. (Do not use pseudocounts; if a transition is not observed, it has a count of 0.)

Write down the following quantities. You may write N/A for undefined quantities.

$\hat{T}(A, \rightarrow, B) =$ ______________________ $\hat{R}(A, \rightarrow, B) =$ ______________________

$\hat{T}(B, \rightarrow, A) =$ ______________________ $\hat{R}(B, \rightarrow, A) =$ ______________________

$\hat{T}(B, \leftarrow, A) =$ ______________________ $\hat{R}(B, \leftarrow, A) =$ ______________________

(c) This question considers properties of reinforcement learning algorithms for *arbitrary* discrete MDPs; you do not need to refer to the MDP considered in the previous parts.

(i) Which of the following methods, at convergence, provide enough information to obtain an optimal policy? (Assume adequate exploration.)

- ☐ Model-based learning of $T(s, a, s')$ and $R(s, a, s')$.
- ☐ Direct Evaluation to estimate $V(s)$.
- ☐ Temporal Difference learning to estimate $V(s)$.
- ☐ Q-Learning to estimate $Q(s, a)$.

(ii) In the limit of infinite timesteps, under which of the following exploration policies is Q-learning guaranteed to converge to the optimal Q-values for all state? (You may assume the learning rate α is chosen appropriately, and that the MDP is ergodic: i.e., every state is reachable from every other state with non-zero probability.)

- ☐ A fixed policy taking actions uniformly at random.
- ☐ A greedy policy.
- ☐ An ϵ-greedy policy
- ☐ A fixed optimal policy.
