Announcements

- Project 1 is due **Friday, September 9, 11:59 PM PT**
  - Start soon if you haven’t already! It’s one of the longer projects.
- HW1 is due **Friday, September 9, 11:59 PM PT**
CS 188: Artificial Intelligence

Constraint Satisfaction Problems

Fall 2022

University of California, Berkeley
What is Search For?

- Assumptions about the world: a single agent, deterministic actions, fully observed state, discrete state space

- Planning: sequences of actions
  - The path to the goal is the important thing
  - Paths have various costs, depths
  - Heuristics give problem-specific guidance

- Identification: assignments to variables
  - The goal itself is important, not the path
  - All paths at the same depth (for some formulations)
  - CSPs are a specialized class of identification problems
Constraint Satisfaction Problems
Constraint Satisfaction Problems

- Standard search problems:
  - State is a “black box”: arbitrary data structure
  - Goal test can be any function over states
  - Successor function can also be anything

- Constraint satisfaction problems (CSPs):
  - A special subset of search problems
  - State is defined by variables $X_i$ with values from a domain $D$ (sometimes $D$ depends on $i$)
  - Goal test is a set of constraints specifying allowable combinations of values for subsets of variables

- Simple example of a formal representation language

- Allows useful general-purpose algorithms with more power than standard search algorithms
Example: Map Coloring

- **Variables:** WA, NT, Q, NSW, V, SA, T
- **Domains:** \( D = \{ \text{red, green, blue} \} \)
- **Constraints:** adjacent regions must have different colors
  - Implicit: WA \(\neq\) NT
  - Explicit: \( (WA, NT) \in \{(\text{red, green}), (\text{red, blue}), \ldots\} \)
- **Solutions are assignments satisfying all constraints,** e.g.:
  \[ \{WA=\text{red}, NT=\text{green}, Q=\text{red}, NSW=\text{green}, V=\text{red}, SA=\text{blue}, T=\text{green}\} \]
Example: N-Queens

Formulation 1:
- Variables: $X_{ij}$
- Domains: $\{0, 1\}$
- Constraints

\[
\forall i, j, k \ (X_{ij}, X_{ik}) \in \{(0, 0), (0, 1), (1, 0)\}, \\
\forall i, j, k \ (X_{ij}, X_{kj}) \in \{(0, 0), (0, 1), (1, 0)\}, \\
\forall i, j, k \ (X_{ij}, X_{i+k,j+k}) \in \{(0, 0), (0, 1), (1, 0)\}, \\
\forall i, j, k \ (X_{ij}, X_{i+k,j-k}) \in \{(0, 0), (0, 1), (1, 0)\}
\]

\[\sum_{i,j} X_{ij} = N\]
Example: N-Queens

- Formulation 2:
  - Variables: $Q_k$
  - Domains: $\{1, 2, 3, \ldots N\}$
  - Constraints:
    - Implicit: $\forall i, j$ non-threatening($Q_i, Q_j$)
    - Explicit: $(Q_1, Q_2) \in \{(1, 3), (1, 4), \ldots\}$
Constraint Graphs
Constraint Graphs

- Binary CSP: each constraint relates (at most) two variables

- Binary constraint graph: nodes are variables, arcs show constraints

- General-purpose CSP algorithms use the graph structure to speed up search. E.g., Tasmania is an independent subproblem!

[Demo: CSP applet (made available by aispace.org) -- n-queens]
Example: Cryptarithmetic

- Variables:
  \[ F \ T \ U \ W \ R \ O \ X_1 \ X_2 \ X_3 \]

- Domains:
  \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}

- Constraints:
  \begin{align*}
  &\text{alldiff}(F, T, U, W, R, O) \\
  &O + O = R + 10 \cdot X_1 \\
  &\ldots
  \end{align*}
Example: Sudoku

- Variables:
  - Each (open) square

- Domains:
  - \{1,2,...,9\}

- Constraints:
  - 9-way alldiff for each column
  - 9-way alldiff for each row
  - 9-way alldiff for each region
  (or can have a bunch of pairwise inequality constraints)
Example: The Waltz Algorithm

- The Waltz algorithm is for interpreting line drawings of solid polyhedra as 3D objects
- An early example of an AI computation posed as a CSP

Approach:
- Each intersection is a variable
- Adjacent intersections impose constraints on each other
- Solutions are physically realizable 3D interpretations
Varieties of CSPs and Constraints
Varieties of CSPs

- **Discrete Variables**
  - Finite domains
    - Size $d$ means $O(d^n)$ complete assignments
    - E.g., Boolean CSPs, including Boolean satisfiability (NP-complete)
  - Infinite domains (integers, strings, etc.)
    - E.g., job scheduling, variables are start/end times for each job
    - Linear constraints solvable, nonlinear undecidable

- **Continuous variables**
  - E.g., start/end times for Hubble Telescope observations
  - Linear constraints solvable in polynomial time by LP methods (see cs170 for a bit of this theory)
Varieties of Constraints

- **Varieties of Constraints**
  - Unary constraints involve a single variable (equivalent to reducing domains), e.g.:
    \[ SA \neq \text{green} \]
  - Binary constraints involve pairs of variables, e.g.:
    \[ SA \neq WA \]
  - Higher-order constraints involve 3 or more variables: e.g., cryptarithmetic column constraints

- **Preferences (soft constraints):**
  - E.g., red is better than green
  - Often representable by a cost for each variable assignment
  - Gives constrained optimization problems
  - (We’ll ignore these until we get to Bayes’ nets)
Real-World CSPs

- Scheduling problems: e.g., when can we all meet?
- Timetabling problems: e.g., which class is offered when and where?
- Assignment problems: e.g., who teaches what class
- Hardware configuration
- Transportation scheduling
- Factory scheduling
- Circuit layout
- Fault diagnosis
- ... lots more!

- Many real-world problems involve real-valued variables...
Solving CSPs
Standard Search Formulation

- Standard search formulation of CSPs

- States defined by the values assigned so far (partial assignments)
  - Initial state: the empty assignment, {} 
  - Successor function: assign a value to an unassigned variable 
  - Goal test: the current assignment is complete and satisfies all constraints

- We’ll start with the straightforward, naïve approach, then improve it
Search Methods

- What would BFS do?
- What would DFS do?
- What problems does naïve search have?

[Demo: coloring -- dfs]
Backtracking Search
Backtracking Search

- Backtracking search is the basic uninformed algorithm for solving CSPs

- **Idea 1: One variable at a time**
  - Variable assignments are commutative, so fix ordering
  - I.e., [WA = red then NT = green] same as [NT = green then WA = red]
  - Only need to consider assignments to a single variable at each step

- **Idea 2: Check constraints as you go**
  - I.e. consider only values which do not conflict with previous assignments
  - Might have to do some computation to check the constraints
  - “Incremental goal test”

- Depth-first search with these two improvements is called *backtracking search* (not the best name)

- Can solve n-queens for $n \approx 25$
Backtracking Example
Backtracking Search

function Backtracking-Search(csp) returns solution/failure
    return Recursive-Backtracking({}, csp)

function Recursive-Backtracking(assignment, csp) returns soln/failure
    if assignment is complete then return assignment
    var ← Select-Unassigned-Variable(VARIABLES[csp], assignment, csp)
    for each value in Order-Domain-Values(var, assignment, csp) do
        if value is consistent with assignment given Constraints[csp] then
            add {var = value} to assignment
            result ← Recursive-Backtracking(assignment, csp)
            if result ≠ failure then return result
            remove {var = value} from assignment
    return failure

- Backtracking = DFS + variable-ordering + fail-on-violation
- What are the choice points?
Improving Backtracking

- General-purpose ideas give huge gains in speed

- Ordering:
  - Which variable should be assigned next?
  - In what order should its values be tried?

- Filtering: Can we detect inevitable failure early?

- Structure: Can we exploit the problem structure?
Filtering
Filtering: Keep track of domains for unassigned variables and cross off bad options

Forward checking: Cross off values that violate a constraint when added to the existing assignment

[Demo: coloring -- forward checking]
Filtering: Constraint Propagation

- Forward checking propagates information from assigned to unassigned variables, but doesn't provide early detection for all failures:

- NT and SA cannot both be blue!
- Why didn’t we detect this yet?
- *Constraint propagation:* reason from constraint to constraint
An arc $X \rightarrow Y$ is **consistent** iff for every $x$ in the tail there is some $y$ in the head which could be assigned without violating a constraint.

Forward checking: Enforcing consistency of arcs pointing to each new assignment.
Arc Consistency of an Entire CSP

- A simple form of propagation makes sure all arcs are consistent:

- Important: If X loses a value, neighbors of X need to be rechecked!
- Arc consistency detects failure earlier than forward checking
- Can be run as a preprocessor or after each assignment
- What’s the downside of enforcing arc consistency?

Remember: Delete from the tail!
Enforcing Arc Consistency in a CSP

function AC-3(csp) returns the CSP, possibly with reduced domains

inputs: csp, a binary CSP with variables \{X_1, X_2, \ldots, X_n\}

local variables: queue, a queue of arcs, initially all the arcs in csp

while queue is not empty do
    (X_i, X_j) ← REMOVE-FIRST(queue)
    if REMOVE-INCONSISTENT-VALUES(X_i, X_j) then
        for each X_k in Neighbors[X_i] do
            add (X_k, X_i) to queue

function REMOVE-INCONSISTENT-VALUES(X_i, X_j) returns true iff succeeds

removed ← false
for each x in DOMAIN[X_i] do
    if no value y in DOMAIN[X_j] allows (x, y) to satisfy the constraint X_i ← X_j
        then delete x from DOMAIN[X_i]; removed ← true

return removed

- Runtime: O(n^2d^3), can be reduced to O(n^2d^2)
- ... but detecting all possible future problems is NP-hard – why?

[Demo: CSP applet (made available by aispace.org) -- n-queens]
Limitations of Arc Consistency

- After enforcing arc consistency:
  - Can have one solution left
  - Can have multiple solutions left
  - Can have no solutions left (and not know it)

- Arc consistency still runs inside a backtracking search!
Ordering
Variable Ordering: Minimum remaining values (MRV):
- Choose the variable with the fewest legal left values in its domain

Why min rather than max?
- Also called “most constrained variable”
- “Fail-fast” ordering
Ordering: Least Constraining Value

- **Value Ordering: Least Constraining Value**
  - Given a choice of variable, choose the *least constraining value*
  - I.e., the one that rules out the fewest values in the remaining variables
  - Note that it may take some computation to determine this! (E.g., rerunning filtering)

- **Why least rather than most?**

- **Combining these ordering ideas makes 1000 queens feasible**

[Demo: coloring – backtracking + AC + ordering]
