CS 188 Spring 2023 Final Review: HMMs & VPI

Q1. Vehicle Perception Indication

A vehicle is trying to identify the situation of the world around it using a set of sensors located around the vehicle.

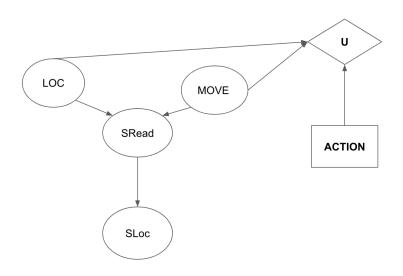

Each sensor reading (SRead) is based off of an object's location (LOC) and an object's movement (MOVE). The sensor reading will then produce various values for its predicted location (SLoc) and predicted movement (SMove). The user will receive these readings, as well as the the image (IMAGE) as feedback.

(a) The vehicle takes an action, and we assign some utility to the action based on the object's location and movement. Possible actions are MOVE TOWARDS, MOVE AWAY, and STOP. Suppose the decision network faced by the vehicle is the following.

- (i) Based on the diagram above, which of the following could possibly be true?
 - \Box VPI (Image) = 0
 - \Box VPI (SRead) < 0
 - \Box VPI (SMove, SRead) > VPI (SRead)
 - \Box VPI (Feedback) = 0
 - \bigcirc None of the above
- (ii) Based on the diagram above, which of the following must necessarily be true?
 - \Box VPI (Image) = 0
 - \Box VPI (SRead) = 0
 - \Box VPI (SMove, SRead) = VPI (SRead)
 - \Box VPI (Feedback) = 0
 - \bigcirc None of the above

Let's assume that your startup has less money, so we use a simpler sensor network. One possible sensor network can be represented as follows.

You have distributions of P(LOC), P(MOVE), P(SRead|LOC, MOVE), P(SLoc|SRead) and utility values U(a, l, m).

(b) Complete the equation for determining the expected utility for some ACTION a.

- (c) Your colleague Bob invented a new sensor to observe values of *SLoc*.
 - (i) Suppose that your company had no sensors till this point. Which of the following expression is equivalent to VPI(SLoc)?
 - $\Box \text{ VPI}(SLoc) = \left(\sum_{sloc} P(sloc) \text{ MEU}(SLoc = sloc)\right) \max_{a} \text{ EU}(a)$
 - $\square VPI(SLoc) = MEU(SLoc) MEU(\emptyset)$
 - $\Box \operatorname{VPI}(SLoc) = \max_{sloc} \operatorname{MEU}(SLoc = sloc) \operatorname{MEU}(\emptyset)$
 - \bigcirc None of the above
 - (ii) Gaagle, an established company, wants to sell your startup a device that gives you *SRead*. Given that you already have Bob's device (that gives you *SLoc*), what is the maximum amount of money you should pay for Gaagle's device? Suppose you value \$1 at 1 utility.

$$\sqcup$$
 VPI(SRead)

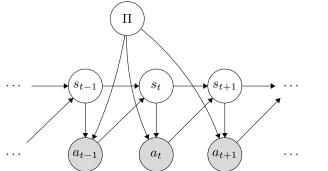

- \Box VPI(*SRead*) VPI(*SLoc*)
- \Box VPI(SRead, SLoc)
- \Box VPI(SRead, SLoc) VPI(SLoc)
- \bigcirc None of the above

2 Particle Filtering Apprenticeship

We are observing an agent's actions in an MDP and are trying to determine which out of a set $\{\pi_1, \ldots, \pi_n\}$ the agent is following. Let the random variable Π take values in that set and represent the policy that the agent is acting under. We consider only *stochastic* policies, so that A_t is a random variable with a distribution conditioned on S_t and Π . As in a typical MDP, S_t is a random variable with a distribution conditioned on S_{t-1} and A_{t-1} . The full Bayes net is shown below.

The agent acting in the environment knows what state it is currently in (as is typical in the MDP setting). Unfortunately, however, we, the observer, cannot see the states S_t . Thus we are forced to use an adapted particle filtering algorithm to solve this problem. Concretely, we will develop an efficient algorithm to estimate $P(\Pi \mid a_{1:t})$.

(a) The Bayes net for part (a) is

- (i) Select all of the following that are guaranteed to be true in this model for t > 3:
 - $\Box S_{t} \perp S_{t-2} \mid S_{t-1}$ $\Box S_{t} \perp S_{t-2} \mid S_{t-1}, A_{1:t-1}$ $\Box S_{t} \perp S_{t-2} \mid \Pi$ $\Box S_{t} \perp S_{t-2} \mid \Pi, A_{1:t-1}$ $\Box S_{t} \perp S_{t-2} \mid \Pi, S_{t-1}$ $\Box S_{t} \perp S_{t-2} \mid \Pi, S_{t-1}$ $\Box S_{t} \perp S_{t-2} \mid \Pi, S_{t-1}, A_{1:t-1}$ $\Box \text{ None of the above}$

We will compute our estimate for $P(\Pi \mid a_{1:t})$ by coming up with a recursive algorithm for computing $P(\Pi, S_t \mid a_{1:t})$. (We can then sum out S_t to get the desired distribution; in this problem we ignore that step.)

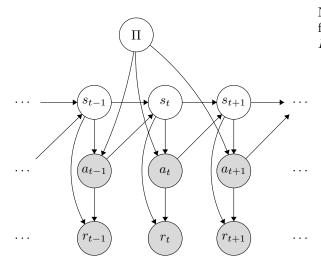

- (ii) Write a recursive expression for $P(\Pi, S_t | a_{1:t})$ in terms of the CPTs in the Bayes net above.
 - $P(\Pi, S_t \mid a_{1:t}) \propto$

We now try to adapt particle filtering to approximate this value. Each particle will contain a single state s_t and a potential policy π_i .

- (iii) The following is pseudocode for the body of the loop in our adapted particle filtering algorithm. Fill in the boxes with the correct values so that the algorithm will approximate $P(\Pi, S_t \mid a_{1:t})$.
 - 1. Elapse time: for each particle (s_t, π_i) , sample a successor s_{t+1} from ______

The policy π' in the new particle is _____.

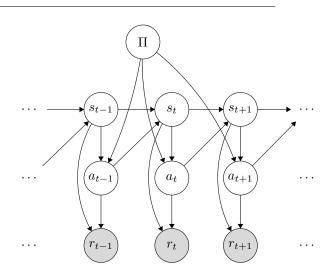

- 2. Incorporate evidence: To each new particle (s_{t+1}, π') , assign weight
- 3. Resample particles from the weighted particle distribution.
- (b) We now observe the acting agent's actions and rewards at each time step (but we still don't know the states). Unlike the MDPs in lecture, here we use a stochastic reward function, so that R_t is a random variable with a distribution conditioned on S_t and A_t . The new Bayes net is given by

Notice that the observed rewards do in fact give useful information since d-separation does not give that $R_t \perp \prod |A_{1:t}$.

(i) Give an active path connecting R_t and Π when A_{1:t} are observed. Your answer should be an ordered list of nodes in the graph, for example "S_t, S_{t+1}, A_t, Π, A_{t-1}, R_{t-1}".

- (ii) Write a recursive expression for $P(\Pi, S_t \mid a_{1:t}, r_{1:t})$ in terms of the CPTs in the Bayes net above.
 - $P(\Pi, S_t \mid a_{1:t}, r_{1:t}) \propto _$
- (c) We now observe *only* the sequence of rewards and no longer observe the sequence of actions. The new Bayes net is shown on the right.

(i) Write a recursive expression for $P(\Pi, S_t, A_t \mid r_{1:t})$ in terms of the CPTs in the Bayes net above.

 $P(\Pi, S_t, A_t \mid r_{1:t}) \propto$

We now try to adapt particle filtering to approximate this value. Each particle will contain a single state s_t , a single action a_t , and a potential policy π_i .

- (ii) The following is pseudocode for the body of the loop in our adapted particle filtering algorithm. Fill in the boxes with the correct values so that the algorithm will approximate $P(\Pi, S_t, A_t | r_{1:t})$.
 - 1. Elapse time: for each particle (s_t, a_t, π_i) , sample a successor state s_{t+1} from _____

Then, sample a successor action a_{t+1} from ______.

The policy π' in the new particle is _____.

- 2. Incorporate evidence: To each new particle (s_{t+1}, a_{t+1}, π') , assign weight ______
- 3. Resample particles from the weighted particle distribution.
