#### Announcements

- Homework 1: Search
  - Has been released! Due Tuesday, Sep 10, at 11:59pm.
    - Electronic component: on Gradescope, instant grading, submit as often as you like.
    - Written component: exam-style template to be completed (we recommend on paper) and to be submitted into Gradescope (graded on effort/completion)
- Project 1: Search
  - Has been released! Due Friday, Sep 13, at 5pm.
  - Start early and ask questions. It's longer than most!
- Sections
  - Starting next week / Monday
  - You can go to any

## CS 188: Artificial Intelligence

Instructors: Pieter Abbeel & Igor Mordatch

University of California, Berkeley

## Today

- Informed Search
  - Heuristics
  - Greedy Search
  - A\* Search

Graph Search

## Recap: Search

## Recap: Search

- Search problem:
  - States (configurations of the world)
  - Actions and costs
  - Successor function (world dynamics)
  - Start state and goal test

#### Search tree:

- Nodes: represent plans for reaching states
- Plans have costs (sum of action costs)
- Search algorithm:
  - Systematically builds a search tree (hopefully only fraction of entire search tree!)
  - Chooses an ordering of the fringe (unexplored nodes)
  - Optimal: finds least-cost plans

#### Example: Pancake Problem

Cost: Number of pancakes flipped

#### **Example: Pancake Problem**

#### **BOUNDS FOR SORTING BY PREFIX REVERSAL**

William H. GATES

Microsoft, Albuquerque, New Mexico

Christos H. PAPADIMITRIOU\*†

Department of Electrical Engineering, University of California, Berkeley, CA 94720, U.S.A.

Received 18 January 1978 Revised 28 August 1978

For a permutation  $\sigma$  of the integers from 1 to *n*, let  $f(\sigma)$  be the smallest number of prefix reversals that will transform  $\sigma$  to the identity permutation, and let f(n) be the largest such  $f(\sigma)$  for all  $\sigma$  in (the symmetric group)  $S_n$ . We show that  $f(n) \leq (5n+5)/3$ , and that  $f(n) \geq 17n/16$  for *n* a multiple of 16. If, furthermore, each integer is required to participate in an even number of reversed prefixes, the corresponding function g(n) is shown to obey  $3n/2 - 1 \leq g(n) \leq 2n + 3$ .

## **Example: Pancake Problem**

State space graph with costs as weights (slide doesn't contain entire state space graph)

### **General Tree Search**

## The One Queue

- All these search algorithms are the same except for fringe strategies
  - Conceptually, all fringes are priority queues (i.e. collections of nodes with attached priorities)
  - Practically, for DFS and BFS, you can avoid the log(n) overhead from an actual priority queue, by using stacks and queues
  - Can even code one implementation that takes a variable queuing object

### **Uninformed Search**

## **Uniform Cost Search**

Strategy: expand lowest path cost

The good: UCS is complete and optimal!

- The bad:
  - Explores options in every "direction"
  - No information about goal location

[Demo: contours UCS pacman small maze (L3D3)]

### **Informed Search**

### **Search Heuristics**

- A heuristic is:
  - A function that *estimates* how close a state is to a goal
  - Designed for a particular search problem
  - Examples: Manhattan distance, Euclidean distance for pathing

### **Example: Heuristic Function**

h(x)

## **Example: Heuristic Function**

Heuristic: the number of the largest pancake that is still out of place

# **Greedy Search**

### **Example: Heuristic Function**

h(x)

## **Greedy Search**

- Strategy: expand a node that you think is closest to a goal state
  - Heuristic: estimate of distance to nearest goal for each state

- A common case:
  - Best-first takes you straight to the (wrong) goal

Worst-case: like a badly-guided DFS

[Demo: contours greedy empty (L3D1)] [Demo: contours greedy pacman small maze (L3D4)]

### A\* Search

## A\* Search

1

## Combining UCS and Greedy

- Uniform-cost orders by path cost, or backward cost g(n)
- Greedy orders by goal proximity, or *forward cost* h(n)

A\* Search orders by the sum: f(n) = g(n) + h(n)

Example: Teg Grenager

#### When should A\* terminate?

Should we stop when we enqueue a goal?

No: only stop when we dequeue a goal

#### Is A\* Optimal?

- What went wrong?
- Actual bad goal cost < estimated good goal cost</p>
- We need estimates to be less than actual costs!

#### **Admissible Heuristics**

## Idea: Admissibility

Inadmissible (pessimistic) heuristics break optimality by trapping good plans on the fringe

Admissible (optimistic) heuristics slow down bad plans but never outweigh true costs

## **Admissible Heuristics**

A heuristic h is admissible (optimistic) if:

 $0 \leq h(n) \leq h^*(n)$ 

#### where $h^*(n)$ is the true cost to a nearest goal

Examples:

 Coming up with admissible heuristics is most of what's involved in using A\* in practice.

## Optimality of A\* Tree Search

### Optimality of A\* Tree Search

### Assume:

- A is an optimal goal node
- B is a suboptimal goal node
- h is admissible

### Claim:

• A will exit the fringe before B

## **Optimality of A\* Tree Search: Blocking**

### Proof:

- Imagine B is on the fringe
- Some ancestor *n* of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B
  - 1. f(n) is less or equal to f(A) -

nBf(n) = g(n) + h(n)Definition of f-cost  $f(n) \le g(A)$ Admissibility of h g(A) = f(A)h = 0 at a goal

# **Optimality of A\* Tree Search: Blocking**

### Proof:

- Imagine B is on the fringe
- Some ancestor *n* of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B
  - 1. f(n) is less or equal to f(A)
  - 2. f(A) is less than f(B) -

g(A) < g(B)f(A) < f(B)

B is suboptimal h = 0 at a goal

# **Optimality of A\* Tree Search: Blocking**

n

B

 $f(n) \le f(A) < f(B)$ 

A

### Proof:

- Imagine B is on the fringe
- Some ancestor *n* of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B
  - 1. f(n) is less or equal to f(A)
  - 2. f(A) is less than f(B)
  - 3. *n* expands before B —
- All ancestors of A expand before B
- A expands before B
- A\* search is optimal

# Properties of A\*

### Properties of A\*

### UCS vs A\* Contours

 Uniform-cost expands equally in all "directions"

 A\* expands mainly toward the goal, but does hedge its bets to ensure optimality

[Demo: contours UCS / greedy / A\* empty (L3D1)] [Demo: contours A\* pacman small maze (L3D5)]

### **Creating Heuristics**

### **Creating Admissible Heuristics**

- Most of the work in solving hard search problems optimally is in coming up with admissible heuristics
- Often, admissible heuristics are solutions to *relaxed problems*, where new actions are available

Inadmissible heuristics are often useful too

### Example: 8 Puzzle

Start State

Actions

**Goal State** 

- What are the states?
- How many states?
- What are the actions?
- How many successors from the start state?
- What should the costs be?

# 8 Puzzle I

- Heuristic: Number of tiles misplaced
- Why is it admissible?
- h(start) = 8
- This is a *relaxed-problem* heuristic

Start State

Goal State

	Average nodes expanded when the optimal path has				
	4 steps	8 steps	12 steps		
UCS	112	6,300	3.6 x 10 <sup>6</sup>		
TILES	13	39	227		

#### Statistics from Andrew Moore

## 8 Puzzle II

- What if we had an easier 8-puzzle where any tile could slide any direction at any time, ignoring other tiles?
- Total Manhattan distance
- Why is it admissible?
- h(start) = 3 + 1 + 2 + ... = 18

Start State

Goal State

	Average nodes expanded when the optimal path has			
	4 steps	8 steps	12 steps	
TILES	13	39	227	
MANHATTAN	12	25	73	

## 8 Puzzle III

- How about using the *actual cost* as a heuristic?
  - Would it be admissible?
  - Would we save on nodes expanded?
  - What's wrong with it?

- With A\*: a trade-off between quality of estimate and work per node
  - As heuristics get closer to the true cost, you will expand fewer nodes but usually do more work per node to compute the heuristic itself

# **Semi-Lattice of Heuristics**

### **Trivial Heuristics, Dominance**

• Dominance:  $h_a \ge h_c$  if

 $\forall n : h_a(n) \geq h_c(n)$ 

- Heuristics form a semi-lattice:
  - Max of admissible heuristics is admissible

 $h(n) = max(h_a(n), h_b(n))$ 

- Trivial heuristics
  - Bottom of lattice is the zero heuristic (what does this give us?)
  - Top of lattice is the exact heuristic

### Graph Search

### Tree Search: Extra Work!

Failure to detect repeated states can cause exponentially more work.

### **Graph Search**

In BFS, for example, we shouldn't bother expanding the circled nodes (why?)

### Graph Search

- Idea: never expand a state twice
- How to implement:
  - Tree search + set of expanded states ("reached set")
  - Expand the search tree node-by-node, but...
  - Before expanding a node, check if the state is in the reached set
    - If in reached set, check the associated cost vs. the new cost
    - Expand if new cost is lower
    - Skip if new cost is higher
- Important: store the reached set as a set of (state, cost) pairs, not a list
- Can graph search wreck completeness? Why/why not?
- How about optimality?

### Importance of tracking state cost in closed set

### Optimality of A\* Graph Search

## A\*: Summary

### A\*: Summary

- A\* uses both backward costs and (estimates of) forward costs
- A\* is optimal with admissible heuristics
- Heuristic design is key: often use relaxed problems

### Tree Search Pseudo-Code

### Graph Search Pseudo-Code

```
function A*-GRAPH-SEARCH(problem, frontier) return a solution or failure
reached \leftarrow an empty dict mapping nodes to the cost to each one
frontier ((MAKE-NODE(INITIAL-STATE[problem]),0), frontier)
while not IS-EMPTY(frontier) do
    node, node.CostToNode \leftarrow POP(frontier)
    if problem.IS-GOAL(node.STATE) then return node
    end if
    if node.STATE is not in reached or reached[node.STATE] > node.CostToNode then
       reached[node.STATE] = node.CostToNode
       for each child-node in EXPAND(problem, node) do
           frontier \leftarrow INSERT((child-node, child-node.COST + CostToNode), frontier)
       end for
   end if
end while
return failure
```

### Consistency of Heuristics\*

- Main idea: estimated heuristic costs ≤ actual costs
  - Admissibility: heuristic cost ≤ actual cost to goal

#### $h(A) \leq actual cost from A to G$

- Consistency: heuristic "arc" cost ≤ actual cost for each arc
  h(A) h(C) ≤ cost(A to C)
- Consequences of consistency:
  - The f value along a path never decreases

 $h(A) \leq cost(A to C) + h(C)$ 

 $f(A) = g(A) + h(A) \le g(A) + cost(A \text{ to } C) + h(C) = f(C)$ 

A\* graph search is optimal

### Only Single State Expansion Needed with Consistent Heuristic\*

- Sketch: consider what A\* does with a consistent heuristic:
  - Fact 1: In tree search, A\* expands nodes in increasing total f value (f-contours)
  - Fact 2: For every state s, nodes that reach s optimally are expanded before nodes that reach s suboptimally
  - Result: A\* graph search is optimal

### First Time State Expansion is Cheapest with Consistent Heuristic\*

### Consider what A\* does:

- Expands nodes in increasing total f value (f-contours)
  Reminder: f(n) = g(n) + h(n) = cost to n + heuristic
- Proof idea: the optimal goal(s) have the lowest f value, so it must get expanded first

There's a problem with this argument. What are we assuming is true?

### First Time State Expansion is Cheapest with Consistent Heuristic\*

#### Proof:

- New possible problem: some n on path to G\* isn't in queue when we need it, because some worse n' for the same state dequeued and expanded first (disaster!)
- Take the highest such *n* in tree
- Let p be the ancestor of n that was on the queue when n' was popped
- f(p) < f(n) because of consistency</pre>
- f(n) < f(n') because n' is suboptimal</p>
- *p* would have been expanded before *n*'
- Contradiction!
