## CS 188: Artificial Intelligence Spring 2010

Lecture 5: CSPs II 2/2/2010

Pieter Abbeel - UC Berkeley Many slides from Dan Klein

#### **Announcements**

- Project 1 due Thursday
- Lecture videos reminder: don't count on it
- Midterm
- Section: CSPs
  - Tue 3-4pm, 285 Cory
  - Tue 4-5pm, 285 Cory
  - Wed 11-noon, 285 Cory
  - Wed noon-1pm, 285 Cory

### Today

- CSPs
- Efficient Solution of CSPs
  - Search
  - Constraint propagation
- Local Search

## Example: Map-Coloring

- Variables: WA, NT, Q, NSW, V, SA, T
- Domain:  $D = \{red, green, blue\}$
- Constraints: adjacent regions must have different colors

 $(WA, NT) \in \{(red, green), (red, blue), (green, red), \ldots\}$ 

Solutions are assignments satisfying all constraints, e.g.:

$$\{WA = red, NT = green, Q = red, \\ NSW = green, V = red, SA = blue, T = green\}$$

# **Constraint Graphs**

- Binary CSP: each constraint relates (at most) two variables
- Binary constraint graph: nodes are variables, arcs show constraints
- General-purpose CSP algorithms use the graph structure to speed up search. E.g., Tasmania is an independent subproblem!

# Example: Cryptarithmetic

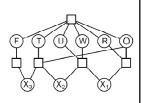

- Variables (circles):
  - $F T U W R O X_1 X_2 X_3$

Domains:

 $\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$ 

Constraints (boxes):  $\mathsf{alldiff}(F, T, U, W, R, O)$ 

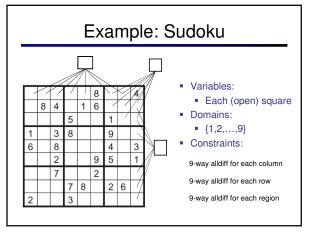

$$O + O = R + 10 \cdot X_1$$

OUR

## Example: The Waltz Algorithm

- The Waltz algorithm is for interpreting line drawings of solid polyhedra
- An early example of a computation posed as a CSP

- Look at all intersections
- Adjacent intersections impose constraints on each other

#### Varieties of CSPs

- Discrete Variables
  - Finite domains
    - Size *d* means O(*d*<sup>n</sup>) complete assignments
    - E.g., Boolean CSPs, including Boolean satisfiability (NP-complete)
  - Infinite domains (integers, strings, etc.)
    - E.g., job scheduling, variables are start/end times for each job
    - Linear constraints solvable, nonlinear undecidable
- Continuous variables
  - E.g., start-end state of a robot
  - Linear constraints solvable in polynomial time by LP methods (see cs170 for a bit of this theory)

#### Varieties of Constraints

- Varieties of Constraints
  - Unary constraints involve a single variable (equiv. to shrinking domains):

 $SA \neq green$ 

· Binary constraints involve pairs of variables:

 $SA \neq WA$ 

- Higher-order constraints involve 3 or more variables: e.g., cryptarithmetic column constraints
- Preferences (soft constraints):
  - E.g., red is better than green
  - Often representable by a cost for each variable assignment Gives constrained optimization problems

(We'll ignore these until we get to Bayes' nets)

#### Real-World CSPs

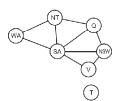

- · Assignment problems: e.g., who teaches what class
- Timetabling problems: e.g., which class is offered when and where?
- Hardware configuration
- Transportation scheduling
- Factory scheduling
- Floorplanning
- Fault diagnosis
- ... lots more!
- Many real-world problems involve real-valued variables...

#### Standard Search Formulation

- Standard search formulation of CSPs (incremental)
- Let's start with the straightforward, dumb approach, then fix it
- States are defined by the values assigned so far
  - Initial state: the empty assignment, {}
  - Successor function: assign a value to an unassigned variable
  - Goal test: the current assignment is complete and satisfies all constraints
- Simplest CSP ever: two bits, constrained to be equal

#### Search Methods

What does BFS do?

- What does DFS do?
  - [demo]
- What's the obvious problem here?
- What's the slightly-less-obvious problem?

## **Backtracking Search**

- Idea 1: Only consider a single variable at each point
  - Variable assignments are commutative, so fix ordering
  - l.e., [WA = red then NT = green] same as [NT = green then WA = red]
     Only need to consider assignments to a single variable at each step
- Idea 2: Only allow legal assignments at each point

  I.e. consider only values which do not conflict previous assignments
- Might have to do some computation to figure out whether a value is ok
   "Incremental goal test"
- Depth-first search for CSPs with these two improvements is called backtracking search (useless name, really)

   [DEMO]
- Backtracking search is the basic uninformed algorithm for CSPs
- Can solve n-queens for  $n \approx 25$

## **Backtracking Search**

 ${\bf function~BACKTRACKING\text{-}SEARCH} (\it csp)~{\bf returns~solution/failure}$  $\mathbf{return} \ \mathsf{Recursive-Backtracking}\big(\big\{\,\big\}, \mathit{csp}\big)$ 

 $\mathbf{function} \ \mathbf{Recursive-Backtracking} (assignment, csp) \ \mathbf{returns} \ \mathbf{soln/failure}$ if assignment is complete then return assignment  $var \leftarrow Select-Unassigned-Variables(Variables[csp], assignment, csp)$ 

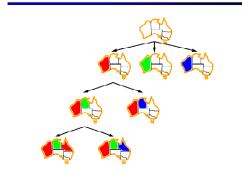

for each value in Order-Domain-Values(var, assignment, csp) do if value is consistent with assignment given Constraints[csp] then

add {var = value} to assignment
result ← Recursive-Backtracking(assignment, csp)  $\textbf{if } \textit{result} \neq \textit{failure } \textbf{then } \textbf{return } \textit{result}$ 

 ${\it remove} \ \{var = value\} \ {\it from} \ assignment$ 

What are the choice points?

## Backtracking Example

# Improving Backtracking

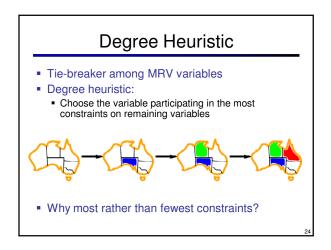

- General-purpose ideas can give huge gains in speed:
  - Which variable should be assigned next?
  - In what order should its values be tried?
  - Can we detect inevitable failure early?
  - Can we take advantage of problem structure?

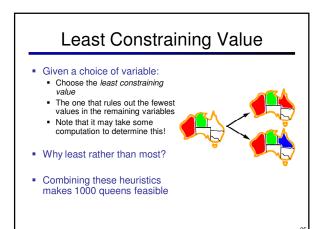

Minimum Remaining Values

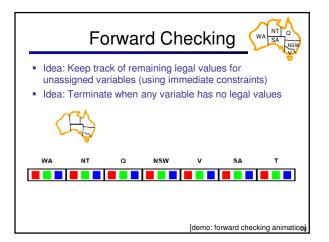

- Minimum remaining values (MRV):
  - Choose the variable with the fewest legal values

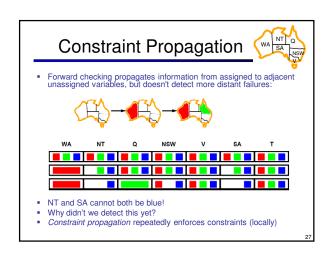

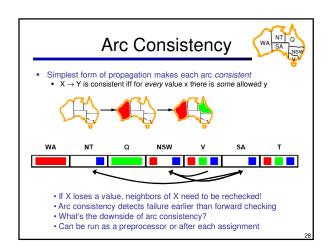

- Why min rather than max?
- Also called "most constrained variable"
- "Fail-fast" ordering

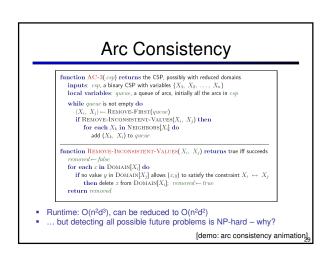

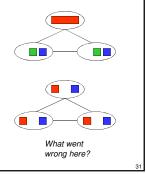

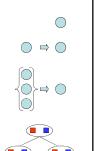

# Limitations of Arc Consistency

- After running arc consistency:
  - Can have one solution left
  - Can have multiple solutions left
  - Can have no solutions left (and not know it)

## K-Consistency

- Increasing degrees of consistency
  - 1-Consistency (Node Consistency):
     Each single node's domain has a value which meets that node's unary constraints
  - Consistency (Arc Consistency): For each pair of nodes, any consistent assignment to one can be extended to the other
  - K-Consistency: For each k nodes, any consistent assignment to k-1 can be extended to the k<sup>th</sup> node.
- Higher k more expensive to compute

# Strong K-Consistency

- Strong k-consistency: also k-1, k-2, ... 1 consistent
- Claim: strong n-consistency means we can solve without backtracking!
- Why?
  - Choose any assignment to any variable
  - Choose a new variable
  - By 2-consistency, there is a choice consistent with the first

  - By 3-consistency, there is a choice consistent with the first 2
- Lots of middle ground between arc consistency and nconsistency! (e.g. path consistency)
