Graph Search

## Recap: Search

## Recap: Search

- Search problem:
  - States (configurations of the world)
  - Actions and costs
  - Successor function (world dynamics)
  - Start state and goal test

#### Search tree:

- Nodes: represent plans for reaching states
- Plans have costs (sum of action costs)
- Search algorithm:
  - Systematically builds a search tree
  - Chooses an ordering of the fringe (unexplored nodes)
  - Optimal: finds least-cost plans

#### Example: Pancake Problem

Cost: Number of pancakes flipped

#### **Example: Pancake Problem**

#### **BOUNDS FOR SORTING BY PREFIX REVERSAL**

William H. GATES

Microsoft, Albuquerque, New Mexico

Christos H. PAPADIMITRIOU\*†

Department of Electrical Engineering, University of California, Berkeley, CA 94720, U.S.A.

Received 18 January 1978 Revised 28 August 1978

For a permutation  $\sigma$  of the integers from 1 to *n*, let  $f(\sigma)$  be the smallest number of prefix reversals that will transform  $\sigma$  to the identity permutation, and let f(n) be the largest such  $f(\sigma)$  for all  $\sigma$  in (the symmetric group)  $S_n$ . We show that  $f(n) \leq (5n+5)/3$ , and that  $f(n) \geq 17n/16$  for *n* a multiple of 16. If, furthermore, each integer is required to participate in an even number of reversed prefixes, the corresponding function g(n) is shown to obey  $3n/2 - 1 \leq g(n) \leq 2n + 3$ .

### **Example: Pancake Problem**

State space graph with costs as weights

### **General Tree Search**

## Informed Search

### **Search Heuristics**

- A heuristic is:
  - A function that *estimates* how close a state is to a goal
  - Designed for a particular search problem
  - Examples: Manhattan distance, Euclidean distance for pathing

#### **Example: Heuristic Function**

h(x)

### **Example: Heuristic Function**

Heuristic: the number of the largest pancake that is still out of place

## Greedy Search

## **Greedy Search**

- Strategy: expand a node that you think is closest to a goal state
  - Heuristic: estimate of distance to nearest goal for each state
- A common case:
  - Best-first takes you straight to the (wrong) goal

Worst-case: like a badly-guided DFS

### A\* Search

### A\* Search

UCS

Greedy

#### **Uniform-Cost Search**

## **Greedy Search**

## Combining UCS and Greedy

- Uniform-cost orders by path cost, or backward cost g(n)
- Greedy orders by goal proximity, or *forward cost* h(n)

A\* Search orders by the sum: f(n) = g(n) + h(n)

## Combining UCS and Greedy

- Uniform-cost orders by path cost, or backward cost g(n)
- Greedy orders by goal proximity, or *forward cost* h(n)

A\* Search orders by the sum: f(n) = g(n) + h(n)

#### When should A\* terminate?

Should we stop when we enqueue a goal?

No: only stop when we dequeue a goal

#### Is A\* Optimal?

- What went wrong?
- Actual bad goal cost < estimated good goal cost</p>
- We need estimates to be less than actual costs!

### **Admissible Heuristics**

## Idea: Admissibility

Inadmissible (pessimistic) heuristics break optimality by trapping good plans on the fringe

Admissible (optimistic) heuristics slow down bad plans but never outweigh true costs

## **Admissible Heuristics**

A heuristic *h* is *admissible* (optimistic) if:

 $0 \leq h(n) \leq h^*(n)$ 

#### where $h^*(n)$ is the true cost to a nearest goal

Examples:

 Coming up with admissible heuristics is most of what's involved in using A\* in practice.

## Optimality of A\* Tree Search

## Optimality of A\* Tree Search

#### Assume:

- A is an optimal goal node
- B is a suboptimal goal node
- h is admissible

#### Claim:

• A will exit the fringe before B

#### Proof:

- Imagine B is on the fringe
- Some ancestor *n* of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B
  - 1. f(n) is less or equal to f(A)

#### 1. f(n) is less than or equal to f(A)

- Definition of f-cost says:
  f(n) = g(n) + h(n) = (path cost to n) + (est. cost of n to A)
  f(A) = g(A) + h(A) = (path cost to A) + (est. cost of A to A)
- The admissible heuristic must underestimate the true cost \_ h(A) = (est. cost of A to A) = 0
- So now, we have to compare:
  f(n) = g(n) + h(n) = (path cost to n) + (est. cost of n to A)
  f(A) = g(A) = (path cost to A)
- h(n) must be an underestimate of the true cost from n to A (path cost to n) + (est. cost of n to A) ≤ (path cost to A)
   g(n) + h(n) ≤ g(A)
   f(n) ≤ f(A)

#### Proof:

- Imagine B is on the fringe
- Some ancestor *n* of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B
  - 1. f(n) is less or equal to f(A)
  - 2. f(A) is less than f(B)

#### 2. f(A) is less than f(B)

We know that:

f(A) = g(A) + h(A) = (path cost to A) + (est. cost of A to A)f(B) = g(B) + h(B) = (path cost to B) + (est. cost of B to B)

- The heuristic must underestimate the true cost:
  h(A) = h(B) = 0
- So now, we have to compare:
  f(A) = g(A) = (path cost to A)
  f(B) = g(B) = (path cost to B)
- We assumed that B is suboptimal! So (path cost to A) < (path cost to B)</li>
   g(A) < g(B)</li>
   f(A) < f(B)</li>

#### Proof:

- Imagine B is on the fringe
- Some ancestor *n* of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B
  - 1. f(n) is less or equal to f(A)
  - 2. f(A) is less than f(B)
  - 3. *n* expands before B
- All ancestors of A expand before B
- A expands before B
- A\* search is optimal

# Properties of A\*

#### Properties of A\*

# UCS vs A\* Contours

 Uniform-cost expands equally in all "directions"

 A\* expands mainly toward the goal, but does hedge its bets to ensure optimality

#### **Creating Heuristics**

## **Creating Admissible Heuristics**

- Most of the work in solving hard search problems optimally is in coming up with admissible heuristics
- Often, admissible heuristics are solutions to *relaxed problems*, where new actions are available

Inadmissible heuristics are often useful too

# Example: 8 Puzzle

Start State

Actions

Image: Constraint of the second seco

2

- What are the states?
- How many states?
- What are the actions?
- How many successors from the start state?
- What should the costs be?

# 8 Puzzle I

- Heuristic: Number of tiles misplaced
- Why is it admissible?
- h(start) = 8
- This is a *relaxed-problem* heuristic

Start State

Goal State

	Average nodes expanded when the optimal path has				
	4 steps	8 steps	12 steps		
UCS	112	6,300	3.6 x 10 <sup>6</sup>		
TILES	13	39	227		

Statistics from Andrew Moore

# 8 Puzzle II

- What if we had an easier 8-puzzle where any tile could slide any direction at any time, ignoring other tiles?
- Total Manhattan distance
- Why is it admissible?
- h(start) = 3 + 1 + 2 + ... = 18

Start State

Goal State

	Average nodes expanded when the optimal path has			
	4 steps	8 steps	12 steps	
TILES	13	39	227	
MANHATTAN	12	25	73	

# 8 Puzzle III

- How about using the *actual cost* as a heuristic?
  - Would it be admissible?
  - Would we save on nodes expanded?
  - What's wrong with it?

- With A\*: a trade-off between quality of estimate and work per node
  - As heuristics get closer to the true cost, you will expand fewer nodes but usually do more work per node to compute the heuristic itself

# **Semi-Lattice of Heuristics**

### **Trivial Heuristics, Dominance**

• Dominance:  $h_a \ge h_c$  if

 $\forall n : h_a(n) \geq h_c(n)$ 

- Heuristics form a semi-lattice:
  - Max of admissible heuristics is admissible

 $h(n) = max(h_a(n), h_b(n))$ 

- Trivial heuristics
  - Bottom of lattice is the zero heuristic (what does this give us?)
  - Top of lattice is the exact heuristic

# Graph Search

#### Tree Search: Extra Work!

Failure to detect repeated states can cause exponentially more work.

### Graph Search

In BFS, for example, we shouldn't bother expanding the circled nodes (why?)

# Graph Search

- Idea: never expand a state twice
- How to implement:
  - Tree search + set of expanded states ("closed set")
  - Expand the search tree node-by-node, but...
  - Before expanding a node, check to make sure its state has never been expanded before
  - If not new, skip it, if new add to closed set
- Important: store the closed set as a set, not a list
- Can graph search wreck completeness? Why/why not?
- How about optimality?

# **Consistency of Heuristics**

- Main idea: estimated heuristic costs ≤ actual costs
  - Admissibility: heuristic cost ≤ actual cost to goal

#### $h(A) \leq actual cost from A to G$

- Consistency: heuristic "arc" cost ≤ actual cost for each arc
   h(A) h(C) ≤ cost(A to C)
- Consequences of consistency:
  - The f value along a path never decreases
    - $h(A) \leq cost(A to C) + h(C)$
  - A\* graph search is optimal

#### Optimality of A\* Graph Search

# Optimality

- Tree search:
  - A\* is optimal if heuristic is admissible
  - UCS is a special case (h = 0)
- Graph search:
  - A\* optimal if heuristic is consistent
  - UCS optimal (h = 0 is consistent)
- Consistency implies admissibility
- In general, most natural admissible heuristics tend to be consistent, especially if from relaxed problems

# A\*: Summary

# A\*: Summary

- A\* uses both backward costs and (estimates of) forward costs
- A\* is optimal with admissible / consistent heuristics
- Heuristic design is key: often use relaxed problems

# Search and Models

- Search operates over models of the world
  - The agent doesn't actually try all the plans out in the real world!
  - Planning is all "in simulation"
  - Your search is only as good as your models...

#### Search Gone Wrong?

#### Search Gone Wrong?

# Appendix: Search Pseudo-Code

#### Tree Search Pseudo-Code

#### Graph Search Pseudo-Code

```
function GRAPH-SEARCH(problem, fringe) return a solution, or failure
   closed \leftarrow an empty set
   fringe \leftarrow \text{INSERT}(\text{MAKE-NODE}(\text{INITIAL-STATE}[problem]), fringe)
   loop do
       if fringe is empty then return failure
       node \leftarrow \text{REMOVE-FRONT}(fringe)
       if GOAL-TEST(problem, STATE[node]) then return node
       if STATE node is not in closed then
           add STATE[node] to closed
           for child-node in EXPAND(STATE[node], problem) do
               fringe \leftarrow \text{INSERT}(child-node, fringe)
           end
   end
```
