CS 188: Artificial Intelligence Naïve Bayes

Instructor: Oliver Grillmeyer --- University of California, Berkeley

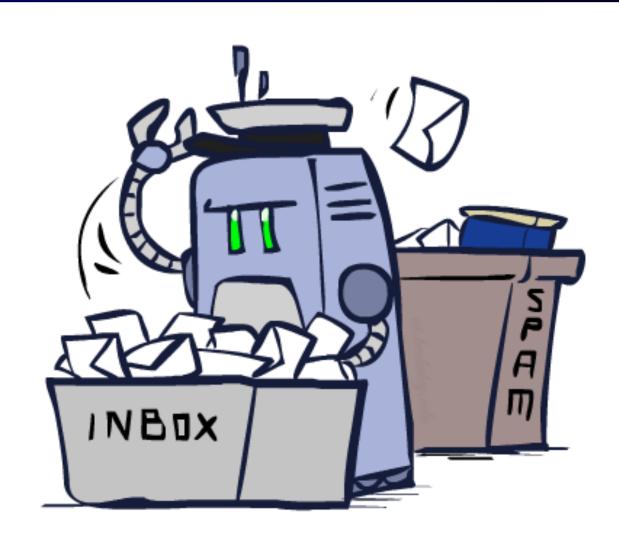

Announcements

- HW7 is due Tuesday, July 29, 11:59 PM PT
- HW8 is due Thursday, July 31, 11:59 PM PT
- Project 4 is due Friday, August 1, 11:59 PM PT
- HW9 is due Tuesday, August 5, 11:59 PM PT
- Ignore assessment on HWs part B, but please show your work
- Final Exam is Wednesday, August 13, 7-10 PM PT
 - Accommodation requests by Wednesday, July 30, 11:59 PM PT

Machine Learning

- Up until now: how to use a model to make optimal decisions
- Machine learning: how to acquire a model from data / experience
 - Learning parameters (e.g. probabilities)
 - Learning structure (e.g. BN graphs)
 - Learning hidden concepts (e.g. clustering, neural nets)
- Today: model-based classification with Naive Bayes

Classification

Example: Spam Filter

Input: an email

Output: spam/ham

- Get a large collection of example emails, each labeled "spam" or "ham"
- Note: someone has to hand label all this data!
- Want to learn to predict labels of new, future emails

■ Words: FREE!

Text Patterns: \$dd, CAPS

Non-text: SenderInContacts, WidelyBroadcast

...

Dear Sir.

First, I must solicit your confidence in this transaction, this is by virture of its nature as being utterly confidencial and top secret. ...

TO BE REMOVED FROM FUTURE MAILINGS, SIMPLY REPLY TO THIS MESSAGE AND PUT "REMOVE" IN THE SUBJECT.

Ok, Iknow this is blatantly OT but I'm beginning to go insane. Had an old Dell Dimension XPS sitting in the corner and decided to put it to use, I know it was working pre being stuck in the corner, but when I plugged it in, hit the power nothing happened.

Example: Digit Recognition

Input: images / pixel grids Output: a digit 0-9	9	0
	1	1
 Get a large collection of example images, each labeled with a digit Note: someone has to hand label all this data! Want to learn to predict labels of new, future digit images 	2	2
Features: The attributes used to make the digit decision • Pixels: (6,8)=ON	/	1
 Shape Patterns: NumComponents, AspectRatio, NumLoops Features are increasingly induced rather than crafted 	O	??

Other Classification Tasks

Classification: given inputs x, predict labels (classes) y

Examples:

Medical diagnosis (input: symptoms,

classes: diseases)

Fraud detection (input: account activity,

classes: fraud / no fraud)

Automatic essay grading (input: document,

classes: grades)

Customer service email routing

Review sentiment

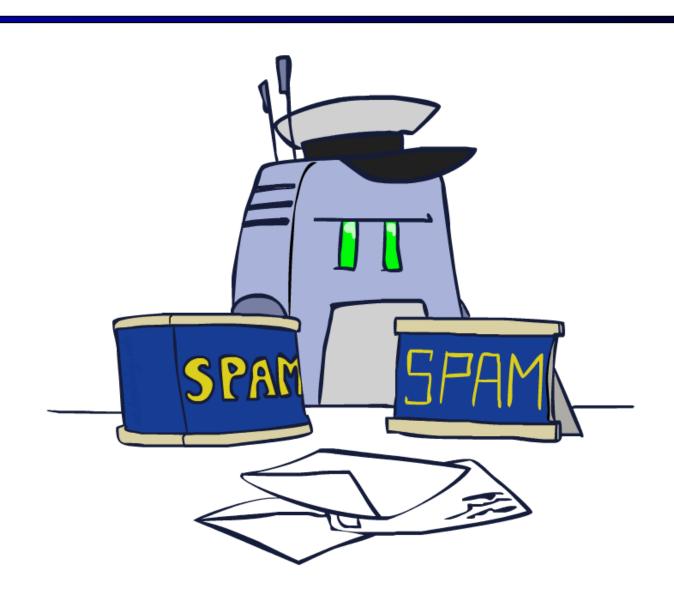

Language ID

... many more

Classification is an important commercial technology!

Model-Based Classification

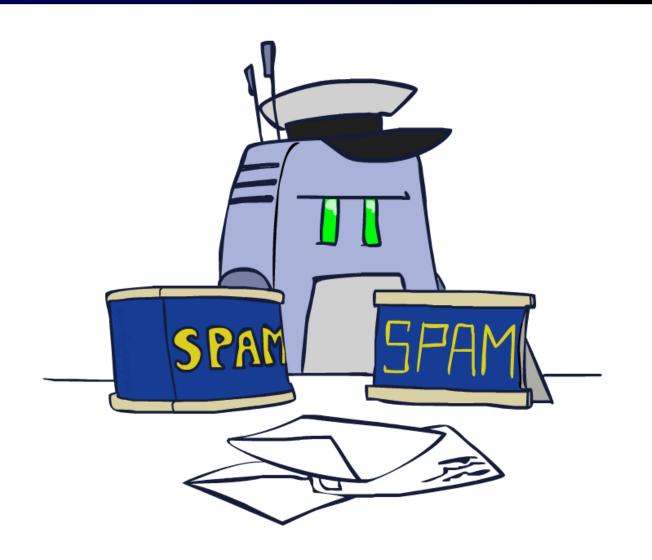

Model-Based Classification

Model-based approach

- Build a model (e.g. Bayes' net) where both the output label and input features are random variables
- Instantiate any observed features
- Query for the distribution of the label conditioned on the features

Challenges

- What structure should the BN have?
- How should we learn its parameters?

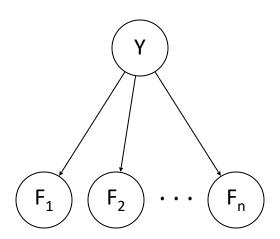

Naïve Bayes for Digits

- Naïve Bayes: Assume all features are independent effects of the label
- Simple digit recognition version:
 - One feature (variable) F_{ii} for each grid position <i,j>
 - Feature values are on / off, based on whether intensity is more or less than 0.5 in underlying image
 - Each input maps to a feature vector, e.g.

- Here: lots of features, each is binary valued
- Naïve Bayes model: $P(Y|F_{0,0}\dots F_{15,15})\propto P(Y)\prod_{i,j}P(F_{i,j}|Y)$
- What do we need to learn?

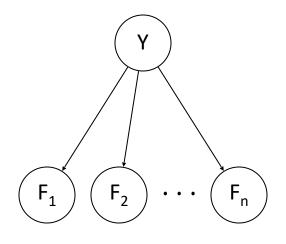

General Naïve Bayes

A general Naive Bayes model:

$$P(Y, F_1 ... F_n) = P(Y) \prod_i P(F_i|Y)$$

$$|Y| \times |F|^n \text{ values} \qquad \qquad \text{n x } |F| \times |Y| \text{ parameters}$$

- We only have to specify how each feature depends on the class
- Total number of parameters is *linear* in n
- Model is very simplistic, but often works anyway

Inference for Naïve Bayes

- Goal: compute posterior distribution over label variable Y
 - Step 1: get joint probability of label and evidence for each label

$$P(Y, f_1 \dots f_n) = \begin{bmatrix} P(y_1, f_1 \dots f_n) \\ P(y_2, f_1 \dots f_n) \\ \vdots \\ P(y_k, f_1 \dots f_n) \end{bmatrix} \longrightarrow \begin{bmatrix} P(y_1) \prod_i P(f_i|y_1) \\ P(y_2) \prod_i P(f_i|y_2) \\ \vdots \\ P(y_k) \prod_i P(f_i|y_k) \end{bmatrix}$$

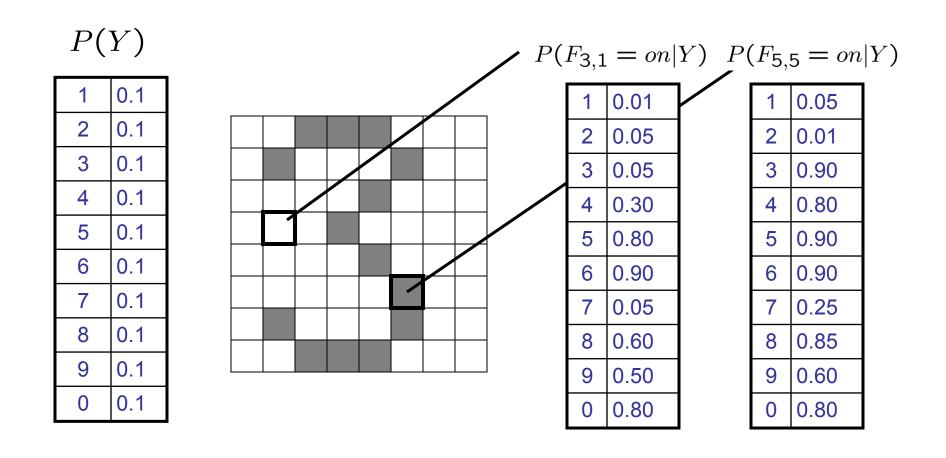

- Step 2: sum to get probability of evidence
- Step 3: normalize by dividing Step 1 by Step 2

$$(Y|f_1 \dots f_n)$$

General Naïve Bayes

- What do we need in order to use Naïve Bayes?
 - Inference method (we just saw this part)
 - Start with a bunch of probabilities: P(Y) and the $P(F_i|Y)$ tables
 - Use standard inference to compute $P(Y|F_1...F_n)$
 - Nothing new here
 - Estimates of local conditional probability tables
 - P(Y), the prior over labels
 - P(F_i|Y) for each feature (evidence variable)
 - \blacksquare These probabilities are collectively called the *parameters* of the model and denoted by θ
 - Up until now, we assumed these appeared by magic, but...
 - ...they typically come from training data counts: we'll look at this soon

Example: Conditional Probabilities

Naïve Bayes for Text

- Bag-of-words Naïve Bayes:
 - Features: W_i is the word at position i
 - As before: predict label conditioned on feature variables (spam vs. ham)
 - As before: assume features are conditionally independent given label
 - New: each W_i is identically distributed

Word at position *i, not ith word in the dictionary!*

- Generative model: $P(Y, W_1 \dots W_n) = P(Y) \prod_i P(W_i|Y)$
- "Tied" distributions and bag-of-words
 - Usually, each variable gets its own conditional probability distribution P(F|Y)
 - In a bag-of-words model
 - Each position is identically distributed
 - All positions share the same conditional probs P(W|Y)
 - Why make this assumption?
 - Called "bag-of-words" because model is insensitive to word order or reordering

Example: Spam Filtering

• Model:
$$P(Y, W_1 \dots W_n) = P(Y) \prod_i P(W_i | Y)$$

What are the parameters?

P(Y)

ham: 0.66 spam: 0.33

P(W|spam)

the: 0.0156
to: 0.0153
and: 0.0115
of: 0.0095
you: 0.0093
a: 0.0086
with: 0.0080
from: 0.0075

$P(W|\mathsf{ham})$

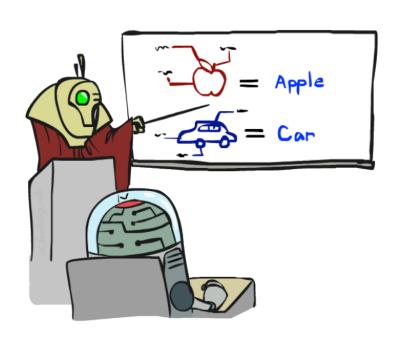

the: 0.0210
to: 0.0133
of: 0.0119
2002: 0.0110
with: 0.0108
from: 0.0107
and: 0.0105
a: 0.0100

Where do these tables come from?

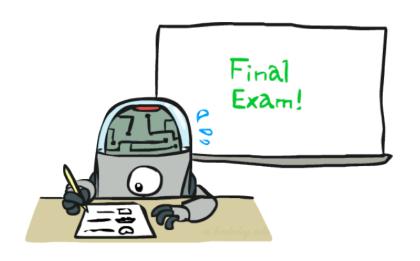

Spam Example

Word	P(w spam)	P(w ham)	Tot Spam	Tot Ham
(prior)	0.33333	0.66666	-1.1	-0.4

Training and Testing

Empirical Risk Minimization

Empirical risk minimization

- Basic principle of machine learning
- We want the model (classifier, etc) that does best on the true test distribution
- Don't know the true distribution so pick the best model on our actual training set
- Finding "the best" model on the training set is phrased as an optimization problem

Main worry: overfitting to the training set

- Better with more training data (less sampling variance, training more like test)
- Better if we limit the complexity of our hypotheses (regularization and/or small hypothesis spaces)

Important Concepts

- Data: labeled instances (e.g. emails marked spam/ham)
 - Training set
 - Held out set
 - Test set
- Features: attribute-value pairs which characterize each x
- Experimentation cycle
 - Learn parameters (e.g. model probabilities) on training set
 - (Tune hyperparameters on held-out set)
 - Compute accuracy of test set
 - Very important: never "peek" at the test set!
- Evaluation (many metrics possible, e.g. accuracy)
 - Accuracy: fraction of instances predicted correctly
- Overfitting and generalization
 - Want a classifier which does well on test data
 - Overfitting: fitting the training data very closely, but not generalizing well
 - We'll investigate overfitting and generalization formally in a few lectures

Training Data

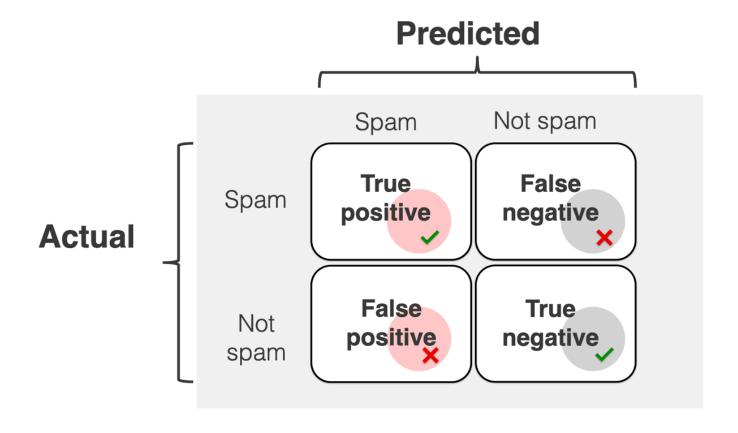

Held-Out Data

> Test Data

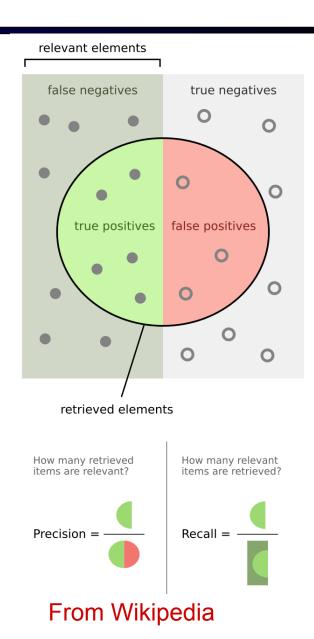

Confusion Matrix

Used to show space of actual and predicted values

From evidentlyai.com

Performance Metrics

Accuracy

Number of correct predictions from the entire data set:
 (TP + TN) / (TP + FP + TN + FN)

Precision

Number of correct positive predictions from total positive predictions:
 TP / (TP + FP)

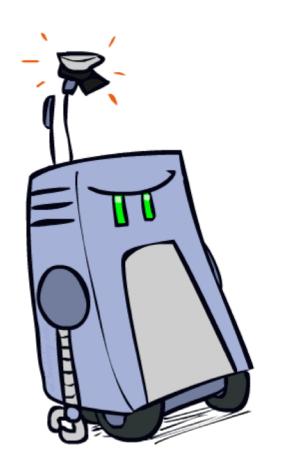

Recall

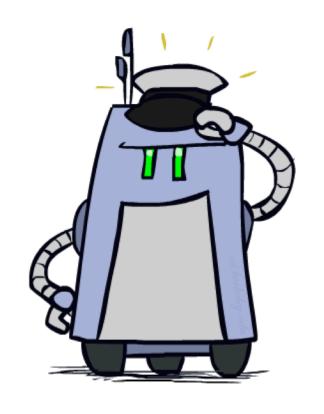

Number of correct positive predictions from the actual positive samples:
 TP / (TP + FN)

F-score

■ Harmonic mean of Precision and Recall: 2TP / (2TP + FP + FN)

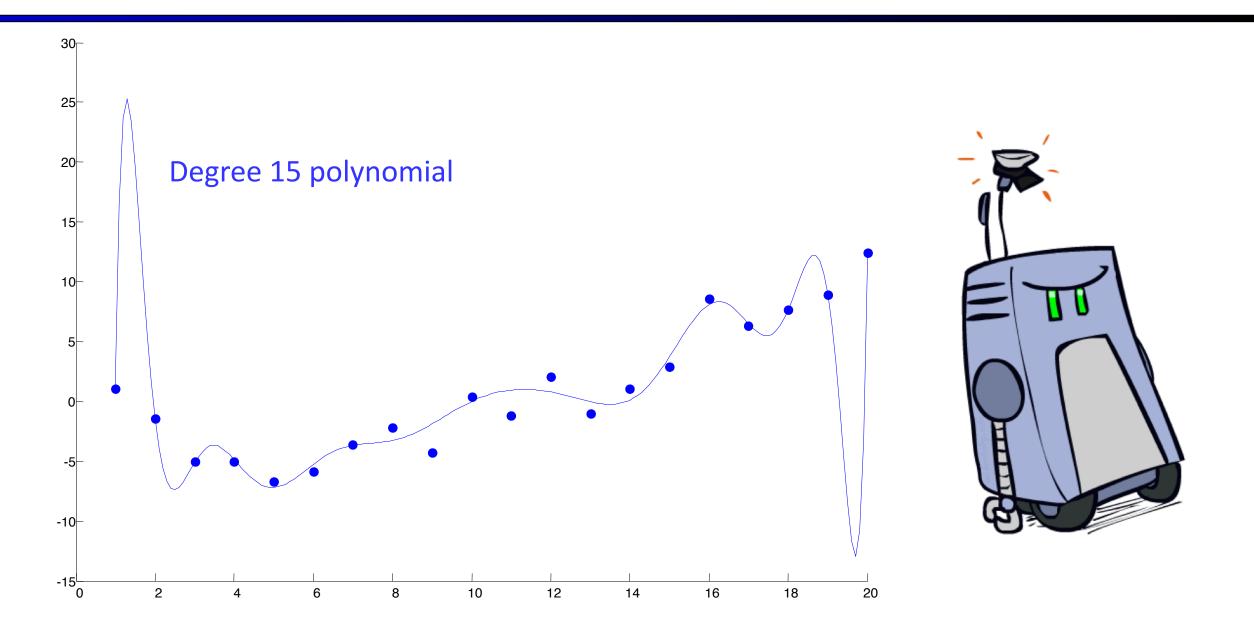

Generalization and Overfitting

Overfitting

Example: Overfitting

$$P(\text{features}, C = 2)$$

$$P(C = 2) = 0.1$$

$$P(\text{on}|C=2) = 0.8$$

$$P(\text{on}|C=2)=0.1$$

$$P(\text{off}|C=2) = 0.1$$

$$P(\mathsf{on}|C=2) = 0.01$$

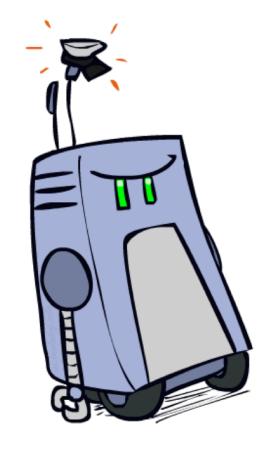

$$P(C = 3) = 0.1$$

$$P(\text{on}|C=3)=0.8$$

$$-P(\text{on}|C=3)=0.9$$

$$P(\text{off}|C=3) = 0.7$$

$$-P(\text{on}|C=3)=0.0$$

2 wins!!

Example: Overfitting

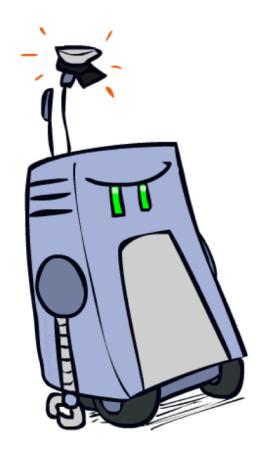

Posteriors determined by relative probabilities (odds ratios):

$$\frac{P(W|\mathsf{ham})}{P(W|\mathsf{spam})}$$

```
south-west : inf
nation : inf
morally : inf
nicely : inf
extent : inf
seriously : inf
```

```
\frac{P(W|\text{spam})}{P(W|\text{ham})}
```

```
screens : inf
minute : inf
guaranteed : inf
$205.00 : inf
delivery : inf
signature : inf
```

What went wrong here?

Generalization and Overfitting

- Relative frequency parameters will overfit the training data!
 - Just because we never saw a 3 with pixel (15,15) on during training doesn't mean we won't see it at test time
 - Unlikely that every occurrence of "minute" is 100% spam
 - Unlikely that every occurrence of "seriously" is 100% ham
 - What about all the words that don't occur in the training set at all?
 - In general, we can't go around giving unseen events zero probability
- As an extreme case, imagine using the entire email as the only feature (e.g. document ID)
 - Would get the training data perfect (if deterministic labeling)
 - Wouldn't generalize at all
 - Just making the bag-of-words assumption gives us some generalization, but isn't enough
- To generalize better: we need to smooth or regularize the estimates

Parameter Estimation

Parameter Estimation

- Estimating the distribution of a random variable
- Elicitation: ask a human (why is this hard?)
- Empirically: use training data (learning!)
 - E.g.: for each outcome x, look at the *empirical rate* of that value:

$$P_{\mathsf{ML}}(x) = \frac{\mathsf{count}(x)}{\mathsf{total samples}}$$

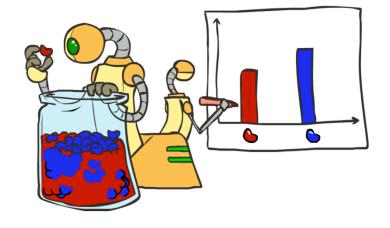

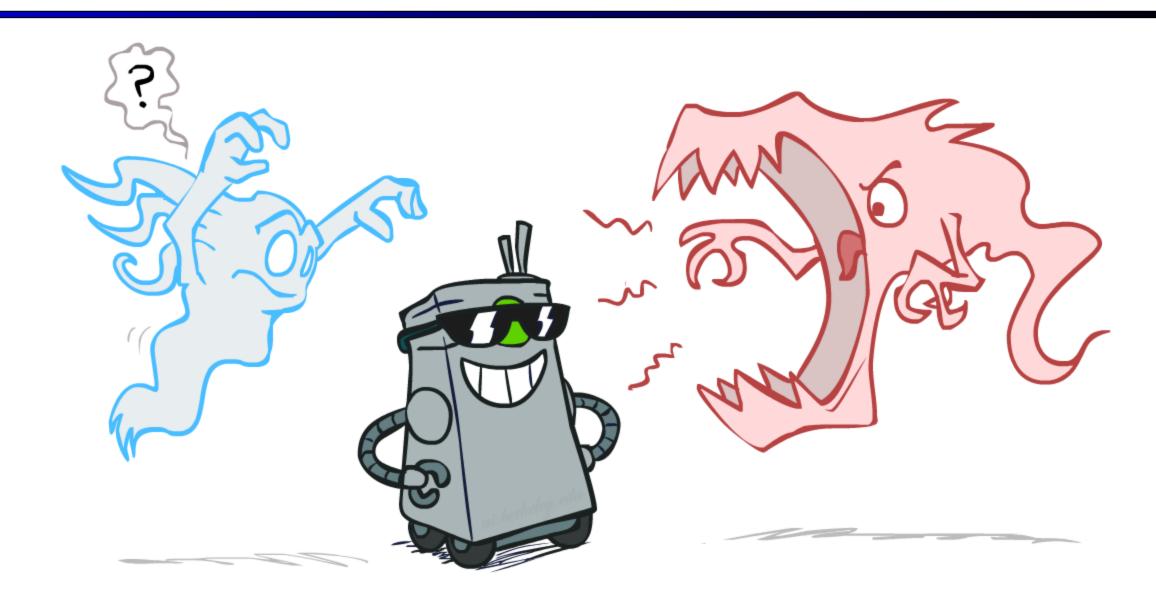

$$P_{\rm ML}({\bf r}) = 2/3$$

■ This is the estimate that maximizes the *likelihood of the data*

$$L(x,\theta) = \prod_{i} P_{\theta}(x_i)$$

Smoothing

Maximum Likelihood?

Relative frequencies are the maximum likelihood estimates

$$\theta_{ML} = \arg\max_{\theta} P(\mathbf{X}|\theta)$$

$$= \arg\max_{\theta} \prod_{i} P_{\theta}(X_{i})$$

$$P_{\text{ML}}(x) = \frac{\text{count}(x)}{\text{total samples}}$$

Another option is to consider the most likely parameter value given the data

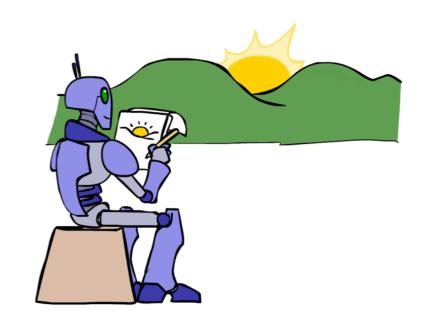

$$\theta_{MAP} = \arg\max_{\theta} P(\theta|\mathbf{X})$$

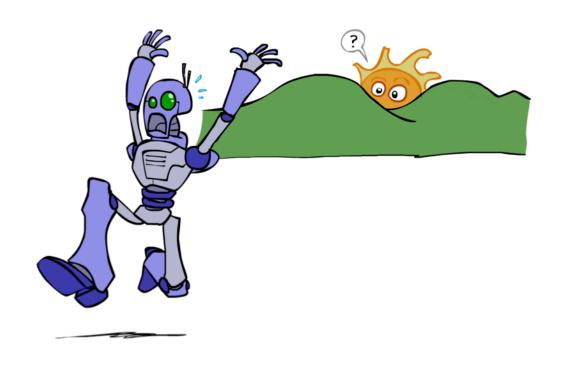

$$= \arg\max_{\theta} P(\mathbf{X}|\theta)P(\theta)/P(\mathbf{X})$$

$$= \arg\max_{\theta} P(\mathbf{X}|\theta)P(\theta)$$

$$= \arg\max_{\theta} P(\mathbf{X}|\theta)P(\theta)$$

Unseen Events

Laplace Smoothing

Laplace's estimate:

 Pretend you saw every outcome once more than you actually did

$$P_{LAP}(x) = \frac{c(x) + 1}{\sum_{x} [c(x) + 1]}$$
$$= \frac{c(x) + 1}{N + |X|}$$

$$P_{ML}(X) =$$

$$P_{LAP}(X) =$$

■ Can derive this estimate with Dirichlet priors (see cs281a)

Laplace Smoothing

- Laplace's estimate (extended):
 - Pretend you saw every outcome k extra times

$$P_{LAP,k}(x) = \frac{c(x) + k}{N + k|X|}$$

- What's Laplace with k = 0?
- k is the strength of the prior

$$P_{LAP,0}(X) =$$

$$P_{LAP,1}(X) =$$

$$P_{LAP,100}(X) =$$

Real NB: Smoothing

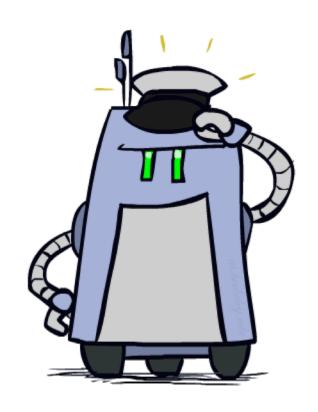

- For real classification problems, smoothing is critical
- New odds ratios:

$$\frac{P(W|\mathsf{ham})}{P(W|\mathsf{spam})}$$

```
helvetica: 11.4
seems: 10.8
group: 10.2
ago: 8.4
areas: 8.3
```

$$\frac{P(W|\text{spam})}{P(W|\text{ham})}$$

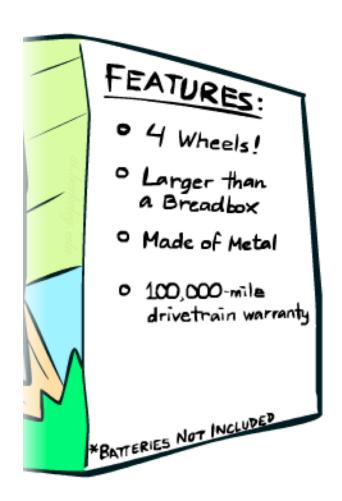

```
verdana : 28.8
Credit : 28.4
ORDER : 27.2
<FONT> : 26.9
money : 26.5
```

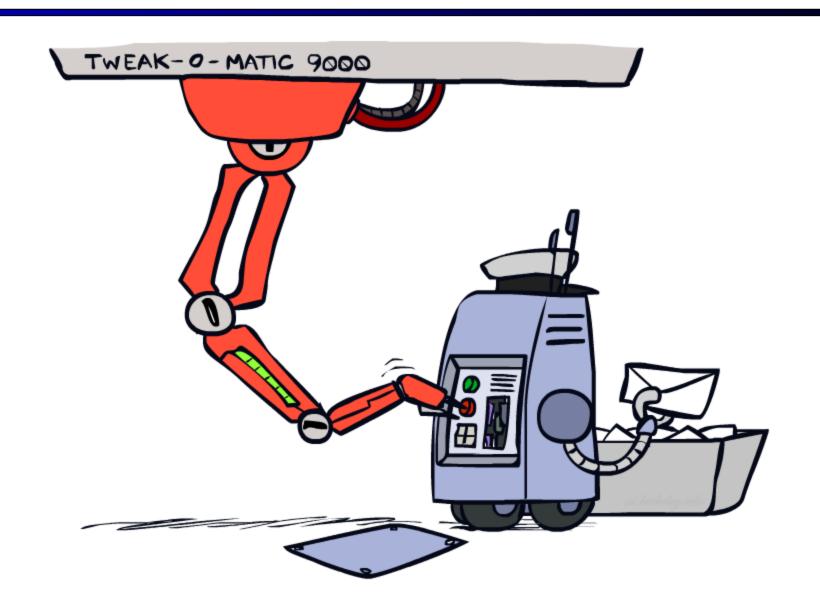

Do these make more sense?

What to Do About Errors?

- Need more features— words aren't enough!
 - Have you emailed the sender before?
 - Have 1K other people just gotten the same email?
 - Is the sending information consistent?
 - Is the email in ALL CAPS?
 - Do inline URLs point where they say they point?
 - Does the email address you by (your) name?
- Can add these information sources as new variables in the Naïve Bayes model
- Next class we'll talk about classifiers which let you easily add arbitrary features more easily, and, later, how to induce new features

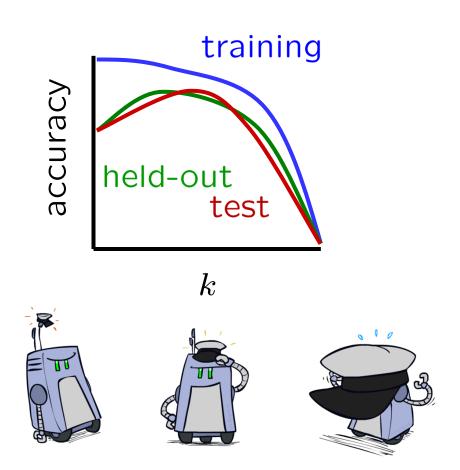

Tuning

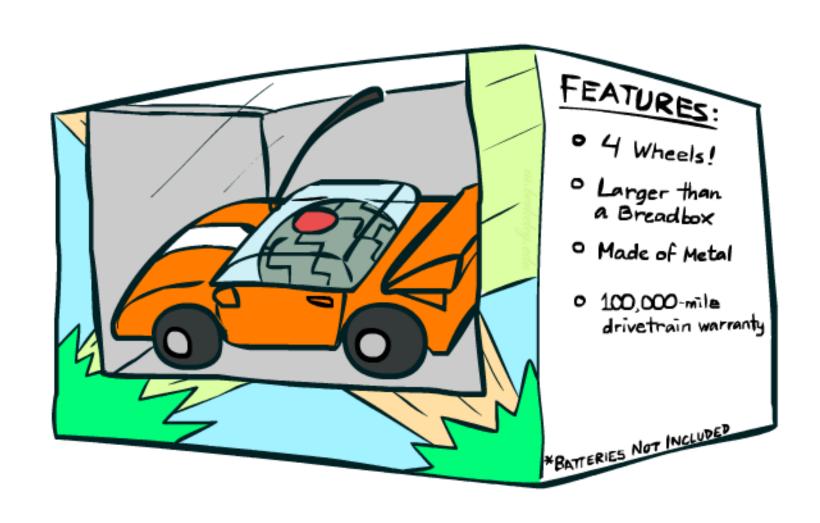

Tuning on Held-Out Data

- Now we've got two kinds of unknowns
 - Parameters: the probabilities P(X|Y), P(Y)
 - Hyperparameters: e.g. the amount / type of smoothing to do, k, α
- What should we learn where?
 - Learn parameters from training data
 - Tune hyperparameters on different data
 - Why?
 - For each value of the hyperparameters, train and test on the held-out data
 - Choose the best value and do a final test on the test data

Features

Errors, and What to Do

Examples of errors

Dear GlobalSCAPE Customer,

GlobalSCAPE has partnered with ScanSoft to offer you the latest version of OmniPage Pro, for just \$99.99* - the regular list price is \$499! The most common question we've received about this offer is - Is this genuine? We would like to assure you that this offer is authorized by ScanSoft, is genuine and valid. You can get the . . .

. . . To receive your \$30 Amazon.com promotional certificate, click through to $% \left(1\right) =\left(1\right) +\left(1\right) +\left($

http://www.amazon.com/apparel

and see the prominent link for the \$30 offer. All details are there. We hope you enjoyed receiving this message. However, if you'd rather not receive future e-mails announcing new store launches, please click . . .

Summary

- Bayes rule lets us do diagnostic queries with causal probabilities
- The naïve Bayes assumption takes all features to be independent given the class label
- We can build classifiers out of a naïve Bayes model using training data
- Smoothing estimates is important in real systems

Next Time: Discriminative Learning
