

# Segmentation of Subspace Arrangements I – Introduction

Allen Y. Yang

Berkeley CS 294-6, Lecture 23

Nov. 20, 2006

## 1 What is a subspace arrangement

- Definition
- Representation

## 2 Converting constraints to subspace arrangements

- Vanishing points
- Affine projections
- Perspective projections
- Approximate nonlinear structures

## 3 Statistical solutions

- K-Means and K-Subspaces
- EM
- RANSAC

# Linear Subspaces and Arrangements

## 1 Linear subspaces

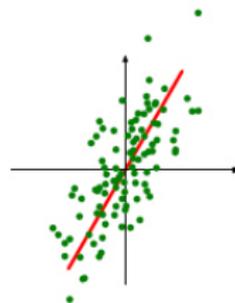

- Subspace structures are widely used for dimension reduction in pattern recognition.
- Linear subspaces pass through the origin, contrary to affine subspaces.
- The classic solution for estimating a subspace for dimension reduction: PCA

**Solution:** Singular Value Decomposition (SVD)

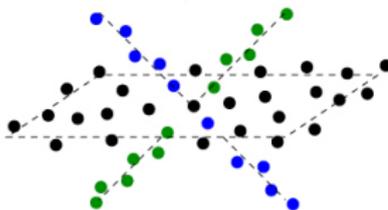

$$U\Sigma V^T = \text{svds}([\mathbf{z}_1, \mathbf{z}_2, \dots, \mathbf{z}_N]_{D \times N}, d), \text{ where } U \in \mathbb{R}^{D \times d}, \Sigma \in \mathbb{R}^{d \times d}, \text{ and } V \in \mathbb{R}^{N \times d}.$$

- $U(:, i)$  is the  $i$ th principal axis (basis vector).
- $c_{ij} = U(:, i)^T \mathbf{z}_j$  is the  $i$ th principal component of  $\mathbf{z}_j$ .
- The projected samples are

$$[\mathbf{z}'_1, \mathbf{z}'_2, \dots, \mathbf{z}'_N] = \Sigma V^T \in \mathbb{R}^{d \times N}.$$

- A subspace arrangement is a collection of linear subspaces in  $\mathbb{R}^D$ , parametrized by the number of subspaces  $K$  and their dimensions  $d_1, d_2, \dots, d_K$ .

## Description of Subspace Arrangements

- 1 Given one subspace  $V \in \mathbb{R}^D$ ,  $\dim(V) = d$ , it is defined by  $d$  basis vectors:

$$V = \text{Span}(\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_d)$$

Now  $\{\mathbf{v}_1, \dots, \mathbf{v}_d\}$  can be expanded to a complete basis of  $\mathbb{R}^D$ :

$$\{\mathbf{v}_1, \dots, \mathbf{v}_d, \mathbf{u}_1, \dots, \mathbf{u}_r\} \text{ where } d + r = D.$$

For any  $\mathbf{z} \in V$ ,  $\mathbf{z} \perp V^\perp \doteq \text{Span}(\mathbf{u}_1, \dots, \mathbf{u}_r)$ :

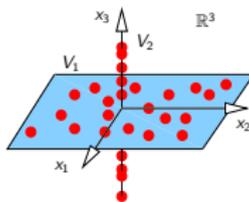

$$\forall \mathbf{z} \in V, (\mathbf{u}_1^T \mathbf{z} = 0) \wedge (\mathbf{u}_2^T \mathbf{z} = 0) \wedge \dots \wedge (\mathbf{u}_r^T \mathbf{z} = 0).$$

- 2 With multiple subspaces  $V_1, V_2, \dots, V_K$ . The arrangement is:

$$\mathcal{A} = V_1 \cup V_2 \cup \dots \cup V_K.$$

Then for any  $\mathbf{z} \in \mathcal{A}$ ,  $(\mathbf{z} \in V_1) \vee (\mathbf{z} \in V_2) \vee \dots \vee (\mathbf{z} \in V_K)$ :

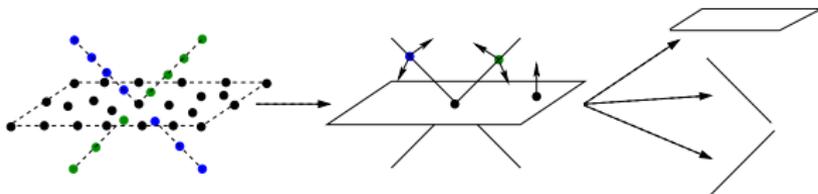

$$\forall \mathbf{z} \in \mathcal{A}, (V_1^\perp{}^T \mathbf{z} = 0) \vee (V_2^\perp{}^T \mathbf{z} = 0) \vee \dots \vee (V_r^\perp{}^T \mathbf{z} = 0).$$

### Punch line

Subspace arrangements are generalization of single subspaces. They are also more compact representation for dimension reduction.

Segmentation of subspace arrangements (subspace-segmentation problem):  
 Given number of subspaces  $K$  and their dimensions  $d_1, \dots, d_K$  known,

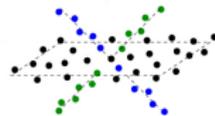

A closer look: There are couples of problems

① Polynomial interpretation:

- $p_j(\mathbf{z}) \doteq \mathbf{u}_j^T \mathbf{z}_i$  is a 1st degree homogeneous polynomial with coefficients  $\mathbf{u}_j$ .
- For a single  $V$ ,  $p_1(\mathbf{z}) = 0, \dots, p_r(\mathbf{z}) = 0$ .

② Noise issue:

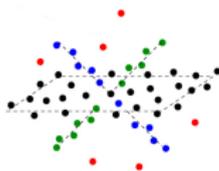

Suppose the measurement  $\tilde{\mathbf{z}} = \mathbf{z} + \mathbf{n}$ , where  $\mathbf{n}$  is (Gaussian) noise.  
 Then  $p_1(\tilde{\mathbf{z}}) \neq 0, \dots, p_r(\tilde{\mathbf{z}}) \neq 0$ .

③ Outlier issue.

Outliers  $\{\mathbf{y}\}$  may appear in the data set, leading to:

$$p_j(\mathbf{y}) \gg 0.$$

④ What to do with affine subspaces?

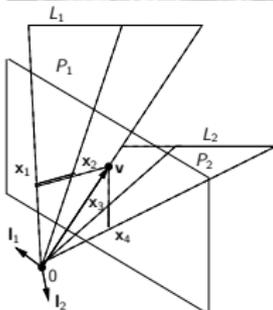

## Vanishing-Point Detection:

- 1 Perspective projection of 2 parallel lines in space intersect at *vanishing point* in image plane.

- 2 Geometry of a family of parallel lines:

- The co-image of a line  $L_1$  is  $\mathbf{l}_1 = \mathbf{x}_1 \times \mathbf{x}_2$ .
  - Given pre-images of two parallel lines  $L_1$  and  $L_2$ ,  $(0, \mathbf{v})$  is on the intersection of  $P_1$  and  $P_2$ .
- ⇒ Any co-image  $\mathbf{l}_i$  of a line parallel to  $L_1$  satisfies:  $\mathbf{l}_i \perp \mathbf{v}$ .

- 3 Multiple vanishing points:

- Multiple families of parallel lines correspond to multiple vanishing points  $\mathbf{v}_1, \dots, \mathbf{v}_n$ .
- Any co-image of a line in the families must satisfy

$$(\mathbf{l}^T \mathbf{v}_1)(\mathbf{l}^T \mathbf{v}_2) \cdots (\mathbf{l}^T \mathbf{v}_n) = 0.$$

⇒ Segmenting parallel line families is equivalent to segmenting 2-D subspaces in  $\mathbb{R}^3$ .

## Motion Segmentation under 3-D Affine Projection

- Affine projection of a single rigid body:
  - Object features  $\mathbf{p}_1, \dots, \mathbf{p}_N \in \mathbb{R}^3$  are tracked in  $F$  frames.

- Denote  $\mathbf{m}_{ij} \in \mathbb{R}^2$  as the image under 3-D affine projection:

$$\mathbf{m}_{ij} = A_j \mathbf{p}_i + \mathbf{b}_j \in \mathbb{R}^2, \quad i = 1, \dots, N; j = 1, \dots, F.$$

- For each  $p_i$ ,

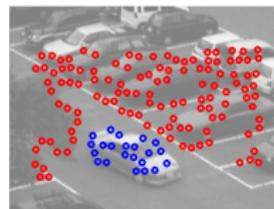

$$\mathbf{z}_i = \begin{bmatrix} \mathbf{m}_{i1} \\ \vdots \\ \mathbf{m}_{iF} \end{bmatrix} \in \mathbb{R}^{2F}, \quad i = 1, \dots, N.$$

- Multibody segmentation:

Given  $K$  independent objects, segment  $\mathbf{z}_1, \dots, \mathbf{z}_N$  that belong to different motions.

$$\Rightarrow \left\{ \begin{array}{ccc} (A_{1,1}, \mathbf{b}_{1,1}) & \cdots & (A_{1,F}, \mathbf{b}_{1,F}) \\ \vdots & \vdots & \vdots \\ (A_{K,1}, \mathbf{b}_{K,1}) & \cdots & (A_{K,F}, \mathbf{b}_{K,F}) \end{array} \right\}.$$

parking-lot movie

Suppose  $\mathbf{p}_1, \dots, \mathbf{p}_N \in \mathbb{R}^3$  are from a single object:

- Stack corresponding images in  $F$  frames:  $\mathbf{z}_i = \begin{bmatrix} m_{i1} \\ m_{i2} \\ \vdots \\ m_{iF} \end{bmatrix} \in \mathbb{R}^{2F}, i = 1, \dots, N$ :

$$W \doteq [\mathbf{z}_1 \cdots \mathbf{z}_N]_{2F \times N} = \begin{bmatrix} A_1 & \mathbf{b}_1 \\ \vdots & \vdots \\ A_F & \mathbf{b}_F \end{bmatrix}_{2F \times 4} \begin{bmatrix} \mathbf{p}_1 & \cdots & \mathbf{p}_N \\ 1 & \cdots & 1 \end{bmatrix}_{4 \times N}.$$

$\Rightarrow \mathbf{z}_i \in \mathbb{R}^{2F}$  lives in a subspace of dimension 4.

- When all  $\mathbf{p}_i$ 's are coplanar, there exists a world coordinate system such that  $\mathbf{p}_i = \begin{bmatrix} x_i \\ y_i \\ 0 \end{bmatrix}$ .

$$W \doteq [\mathbf{z}_1 \cdots \mathbf{z}_N]_{2F \times N} = \begin{bmatrix} A_1 & \mathbf{b}_1 \\ \vdots & \vdots \\ A_F & \mathbf{b}_F \end{bmatrix}_{2F \times 4} \begin{bmatrix} x_1 & \cdots & x_N \\ y_1 & \cdots & y_N \\ 0 & \cdots & 0 \\ 1 & \cdots & 1 \end{bmatrix}_{4 \times N}.$$

$\Rightarrow \mathbf{z}_i \in \mathbb{R}^{2F}$  lives in a subspace of dimension 3.

### Multiple rigid bodies under affine projection

Segmenting multiple rigid bodies under affine camera projection is equivalent to segmenting multiple subspaces of dimension 3 or 4.

## Perspective projections (bilinear constraints)

- Consider *one* epipolar constraint:

$$\rho(\mathbf{x}_1, \mathbf{x}_2) = \mathbf{x}_2^T F \mathbf{x}_1 = 0,$$

which is a bilinear constraint on  $(\mathbf{x}_1, \mathbf{x}_2)$ .

- For  $N$  epipolar constraints,

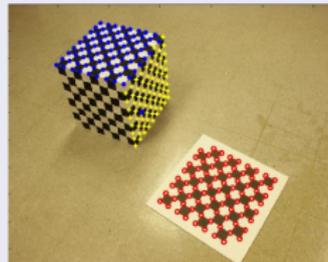

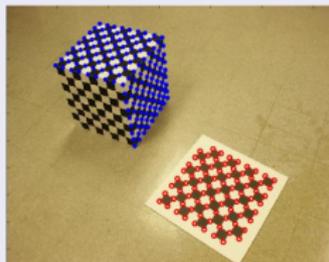

$$(\mathbf{x}_2^T F_1 \mathbf{x}_1)(\mathbf{x}_2^T F_2 \mathbf{x}_1) \cdots (\mathbf{x}_2^T F_N \mathbf{x}_1) = 0.$$

- Similar techniques exist to convert bilinear constraints to a subspace-segmentation problem:

$$\mathbf{x}_2^T F_i \mathbf{x}_1 \Leftrightarrow (\mathbf{x}_1 \otimes \mathbf{x}_2)^T F_i^s = 0.$$

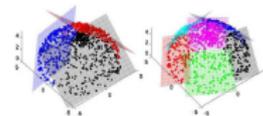

### Multiple rigid bodies under perspective projection

Segmenting multiple rigid bodies under perspective projection (bilinear constraints) can be converted to a subspace segmentation problem.

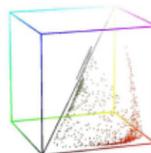

Be careful about degenerate structures:

## Approximate nonlinear structures

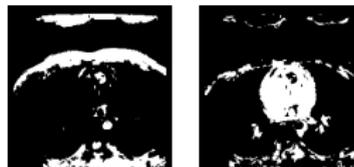

- Processing image and video data: **Critical to handle large non-Gaussian noise by nonlinear structures.**

- Image Segmentation

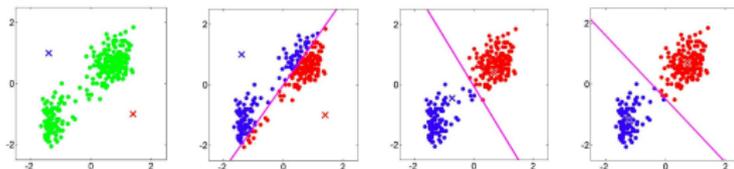

- Dynamic Texture Segmentation

Heart

## K-Means and K-Subspaces

- K-Means for segmenting  $K$  Gaussian clusters:

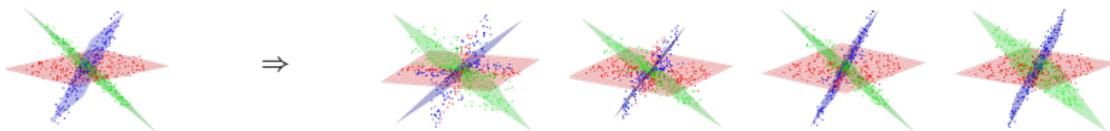

- K-Subspaces for subspace arrangements [Ho et al., 2003]:

- 1 Initialization: Set initial values of orthogonal matrices  $\hat{U}_i^{(0)} \in \mathbb{R}^{D \times d_i}$  for  $i = 1, \dots, N$ . Let  $m = 0$ .
- 2 Segmentation: For each sample  $\mathbf{z}_k$ , assign it to group  $\hat{X}_i^{(m)}$  if

$$i = \arg \min_i \|\mathbf{z}_k - \hat{U}_i^{(m)} (\hat{U}_i^{(m)})^T \mathbf{z}_k\|^2.$$

- 3 Estimation: Apply PCA to each subset  $\hat{X}_i^{(m)}$  and obtain new estimates for the subspace bases  $\hat{U}_i^{(m+1)}$ .
- 4 Let  $m \leftarrow m + 1$ , and repeat step 2 and 3 until the segmentation does not change.

- **Question:** What is your estimate of where the local minima are?

## Expectation-Maximization

- Setup:

- 1 Given  $\{\mathbf{z}_1, \dots, \mathbf{z}_N\}$ , amend a latent membership for each sample  $(\mathbf{z}_i, \eta_i) \in \mathbb{R}^D \times \mathbb{N}$  and a probability  $\pi_{i,j} \doteq p(\eta_i = j)$ .
- 2 Assume a Gaussian noise model for each subspace model  $\theta_i = (B_i, \sigma_i, \pi_i)$ :

$$p(\mathbf{z}|\eta = i) \doteq \frac{1}{(2\pi)^{(D-d_i)/2} \sigma_i} \exp\left(-\frac{\mathbf{z}^T B_i B_i^T \mathbf{z}}{2\sigma_i^2}\right),$$

where  $B_i \in \mathbb{R}^{D \times (D-d_i)}$  is a orthogonal matrix.

- Algorithm:

- 1 Initialization: Set initial values for  $\hat{\theta}_i^{(0)} = \{\hat{B}_i^{(0)}, \hat{\sigma}_i^{(0)}, \hat{\pi}_i^{(0)}\}$  for  $i = 1, \dots, n$ . Set  $m = 0$ .
- 2 Expectation: Compute the expected value of  $w_{ik}$  as

$$w_{ik}^{(m)} \doteq p(\eta_k = i | \mathbf{z}_k, \hat{\theta}^{(m)}) = \frac{\hat{\pi}_i^{(m)} p(\mathbf{z}_k | \eta_k = i, \hat{\theta}^{(m)})}{\sum_{l=1}^N \hat{\pi}_l^{(m)} p(\mathbf{z}_k | \eta_k = l, \hat{\theta}^{(m)})}. \quad (1)$$

- 3 Maximization: Using the expected values  $w_{ij}^{(m)}$ , compute  $\hat{\theta}^{(m+1)}$ .

$$\begin{aligned} \hat{B}_i^{(m+1)} &= \text{the eigenvectors associated with the smallest } D - d_i \text{ eigenvalues of} \\ &\quad \text{the matrix } \sum_{k=1}^n w_{ik}^{(m)} \mathbf{z}_k \mathbf{z}_k^T. \\ \hat{\pi}_i^{(m+1)} &= \frac{\sum_{k=1}^n w_{ik}^{(m)}}{\sum_{k=1}^n w_{ik}^{(m)}}. \\ (\hat{\sigma}_i^{(m+1)})^2 &= \frac{\sum_{k=1}^n w_{ik}^{(m)} \|(\hat{B}_i^{(m+1)})^T \mathbf{z}_k\|^2}{(D-d_i) \sum_{k=1}^n w_{ik}^{(m)}}. \end{aligned} \quad (2)$$

- 4 Let  $m \leftarrow m + 1$ , and repeat step 2 and 3 until the update in the parameters is small enough.

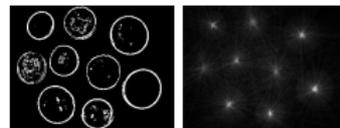

## Random Sample Consensus (RANSAC)

- Consensus-based algorithms:

*Hough*: [Ballard 1981, Lowe 1999]

*RANSAC*: [Fischler & Bolles 1981, Torr 1997]

*Least Median Estimate (LME)*: [Rousseeuw 1984, Steward 1999]

- Estimating subspace arrangements via RANSAC

- RANSAC-on-Union**: Simultaneously estimation multiple subspaces.

Complexity: Subspaces (2, 2, 2) with samples (200, 200, 200). Probability for a good sample set:

$$\frac{(200 \cdot 199)^3 3!}{600 \cdot 599 \cdots 595} = 0.8\%.$$

- RANSAC-on-Subspaces**: Estimate one subspace at a time.

Complexity: Subspaces (2, 2, 2) with samples (200, 200, 200). Probability for a good sample set:

$$\frac{3(200 \cdot 199)}{600 \cdot 599} = 33\%.$$

- RANSAC-on-Subspaces with subspace degeneracy detection

- Start with the highest-dimensional model. Find a sample subset with highest consensus.
- Verify if the subset can be fitted with lower-dimensional models. If so, **temporarily discard the samples, and re-estimate the model from the remaining samples.**
