# CS 61A Lecture 12 Monday, September 29

### Announcements

- \*Homework 3 due Wednesday 10/1 @ 11:59pm
- \*Homework Party on Monday 9/29, time and place TBD
- •Optional Hog Contest due Wednesday 10/1 @ 11:59pm
- •Project 2 due Thursday 10/9 @ 11:59pm

## Box-and-Pointer Notation

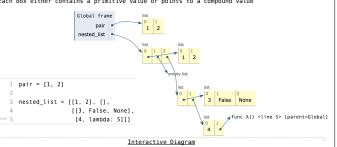

## The Closure Property of Data Types

- A method for combining data values satisfies the closure property if:
- The result of combination can itself be combined using the same method.
- $\bullet$  Closure is the key to power in any means of combination because it permits us to create hierarchical structures.
- $^{\bullet}$  Hierarchical structures are made up of parts, which themselves are made up of parts, and so on.

Lists can contain lists as elements

# Box-and-Pointer Notation in Environment Diagrams Lists are represented as a row of index-labeled adjacen

Lists are represented as a row of index-labeled adjacent boxes, one per element Each box either contains a primitive value or points to a compound value

Trees

# 

# Tree Processing Uses Recursion

(Demo)

Processing a leaf is often the base case of a tree processing function  $% \left( 1\right) =\left( 1\right) \left( 1\right) \left($ 

The recursive case often makes a recursive call on each branch and then aggregates  ${\sf case}$ 

```
def count_leaves(tree):
    """Count the leaves of a tree."""
    if is_leaf(tree):
        return 1
    else:
        branch_counts = [count_leaves(b) for b in tree]
        return sum(branch_counts)
```

# Complete the definition of flatten, which takes a tree and returns a list of its leaves Hint: If you sum a sequence of lists, you get 1 list containing the elements of those lists >>> sum([[1], [2, 3], [4]], []) | (11, 2, 3, 4] | >>> sum([[1]], []) | (21, 2, 3, 4] | >>> sum([[1]], [2]], []) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) | (21, 2, 3, 4, 5, 6, 7) |

```
Sequence Operations
```

```
Trees may also have restrictions on their structure

A binary tree is either a leaf or a sequence containing at most two binary trees

The process of transforming a tree into a binary tree is called binarization

def right_binarize(tree):
    """Construct a right-branching binary tree.

>>> right_binarize([1, 2, 3, 4, 5, 6, 7])
    [1, [2, [3, [4, [5, [6, 7]]]]]]
    """

if is_leaf(tree):
    return tree
    if len(tree) > 2:
        tree = [tree[0], (tree[1:]]]
    return [right_binarize(b) for b in tree]

(Demo)
```

```
Strings
```

```
Strings are an Abstraction

Representing data:

'200' '1.2e-5' 'False' '(1, 2)'

Representing language:

"""And, as imagination bodies forth
The forms of things to unknown, and the poet's pen
Turns them to shapes, and gives to airy nothing
A local habitation and a name.

Representing programs:

'curry = lambda f: lambda x: lambda y: f(x, y)'

(Demo)
```

```
String Literals Have Three Forms

>>> 'I am string!'
'I am string!'
>>> "I've got an apostrophe"
Single-quoted and double-quoted strings are equivalent
>>> '您好'
'您好'

>>> """The Zen of Python claims, Readability counts, Read more: import this.""
'The Zen of Python\nclaims, Readability counts.
Read more: import this.""

A backslash "escapes" the following character represents a new line
```

# Dictionaries

{'Dem': 0}

## Limitations on Dictionaries

Dictionaries are unordered collections of key-value pairs

Dictionary keys do have two restrictions:

- ullet A key of a dictionary **cannot be** a list or a dictionary (or any  $\mathit{mutable\ type}$ )
- Two **keys cannot be equal;** There can be at most one value for a given key

This first restriction is tied to Python's underlying implementation of dictionaries

The second restriction is part of the dictionary abstraction

If you want to associate multiple values with a key, store them all in a sequence value  $% \left( \frac{1}{2}\right) =\left( \frac{1}{2}\right) ^{2}$
