Announcements

Scheme

Scheme is a Dialect of Lisp

What are people saying about Lisp?

"If you don't know Lisp, you don't know what it means for a programming language to be powerful and elegant."

- Richard Stallman, created Emacs & the first free variant of UNIX

"The only computer language that is beautiful."

- Neal Stephenson, DeNero's favorite sci-fi author

"The greatest single programming language ever designed."

- Alan Kay, co-inventor of Smalltalk and OOP (from the user interface video)

Scheme Values

Scheme values include (among others):

ATOMS

- Numbers (in our dialect, integers and floating-point values).
- Booleans
- Symbols (much like strings, but with equal strings being the same object).
- The value nil (like Python None).
- Functions.

COMPOSITE VALUES

- Pairs (like two-element Python lists).
- Scheme lists formed from pairs and nil, as for our linked lists.

Big Idea: Scheme Programs Are Scheme Values

Numbers and nil represent literals.

Symbols represent variables.

Lists (formed from pairs) represent everything else.

Since Scheme programs compute Scheme values, they can construct Scheme programs as well.

Scheme Expressions

Scheme programs consist of expressions, which can be:

- Primitive expressions: 2 3.3 true + quotient
- Combinations: (quotient 10 2) (not true)

Numbers are self-evaluating; symbols are bound to values

Call expressions include an operator and 0 or more operands in parentheses

```
> (quotient 10 2)
5
> (quotient (+ 8 7) 5)
3
> (+ 3
  (* 2 4)
  (+ 3 5)))
16
> (- 10 7)
3
```

"quotient" names Scheme's built-in integer division procedure (i.e., function)

Combinations can span multiple lines (spacing doesn't matter)

(Demo)

Special Forms

Special Forms

A combination that is not a call expression is a special form:

- **if** expression: (if <predicate> <consequent> <alternative>)
- **and** and **or**: (and <e1> ... <en>), (or <e1> ... <en>)
- **Binding symbols**: (define <symbol> <expression>)
- **New procedures**: (define (<symbol> <formal parameters>) <body>)

Evaluation:
(1) Evaluate the predicate expression
(2) Evaluate either the consequent or alternative

```
> (define pi 3.14)
> (* pi 2)
6.28
> (define (abs x)
  (if (< x 0)
      (- x)
      x))
> (abs -3)
3
```

The symbol "pi" is bound to 3.14 in the global frame

A procedure is created and bound to the symbol "abs"

Scheme Interpreters

(Demo)

Lambda Expressions

Lambda Expressions

Lambda expressions evaluate to anonymous procedures

(lambda (<formal-parameters>) <body>)

Two equivalent expressions:

(define (plus4 x) (+ x 4))

(define plus4 (lambda (x) (+ x 4)))

An operator can be a call expression too:

```
((lambda (x y z) (+ x y (square z))) 1 2 3) 12
```

Evaluates to the x+y+z² procedure

Pairs and Lists

- In the late 1950s, computer scientists used confusing names
- **cons**: Two-argument procedure that creates a pair (cons 1 2)
 - **car**: Procedure that returns the first element of a pair (cons 2 nil)
 - **cdr**: Procedure that returns the second element of a pair
 - **nil**: The empty list
 - A (non-empty) list in Scheme is a pair in which the second element is **nil** or a Scheme list
 - **Important!** Scheme lists are written in parentheses separated by spaces
 - A dotted list has some value for the second element of the last pair that is not a list

```
> (cons 1 (cons 2 nil))
(1 2)
> (define x (cons 1 2))
> x
(1 . 2)
> (car x)
1
> (cdr x)
2
> (cons 1 (cons 2 (cons 3 (cons 4 nil))))
(1 2 3 4)
```

Not a well-formed list!

(Demo)

Symbolic Programming

Symbolic Programming

Symbols normally refer to values; how do we refer to symbols?

```
> (define a 1)
> (define b 2)
> (list a b)
(1 2)
```

No sign of "a" and "b" in the resulting value

Quotation is used to refer to symbols directly in Lisp.

```
> (list 'a 'b)
(a b)
> (list 'a b)
(a 2)
```

Short for (quote a), (quote b): Special form to indicate that the symbol itself is the value.

Quotation can also be applied to combinations to form lists.

```
> (car '(a b c))
a
> (cdr '(a b c))
(b c)
```

Scheme Lists and Quotation

Dots can be used in a quoted list to specify the second element of the final pair.

```
> (cdr (cdr '(1 2 . 3)))  
3
```

However, dots appear in the output only of ill-formed lists.

```
> '(1 2 . 3)  
(1 2 . 3)  
> '(1 2 . (3 4))  
(1 2 3 4)  
> '(1 2 3 . nil)  
(1 2 3)
```

What is the printed result of evaluating this expression?

```
> (cdr '((1 2) . (3 4 . (5))))  
(3 4 5)
```
