

Data Abstraction

- Compound values combine other values together
 - A date: a year, a month, and a day
 - A geographic position: latitude and longitude
- Data abstraction lets us manipulate compound values as units
- Isolate two parts of any program that uses data:
 - -How data are represented (as parts)
 - •How data are manipulated (as units)
- Data abstraction: A methodology by which functions enforce an abstraction barrier between representation and use

Rational Numbers

numerator

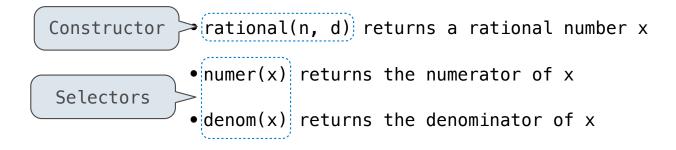

denominator

Exact representation of fractions

A pair of integers

As soon as division occurs, the exact representation may be lost! (Demo)

Assume we can compose and decompose rational numbers:

5

Rational Number Arithmetic

$$\frac{3}{2} * \frac{3}{5} = \frac{9}{10}$$

$$\frac{3}{2} + \frac{3}{5} = \frac{21}{10}$$

Example

$$\begin{array}{cccc}
 & nx & ny & nx*ny \\
\hline
 & dx & dy & dx*dy
\end{array}$$

$$\frac{nx}{---} + \frac{ny}{---} = \frac{nx*dy + ny*dx}{dx*dy}$$

General Form

Rational Number Arithmetic Implementation

```
def mul_rational(x, y):
    return rational(numer(x) * numer(y),
                    denom(x) * denom(y)
                                                                   ny
                                                                                 nx*ny
                                                        nx
      Constructor
                                                        dx
                                                                   dy
                                                                                 dx*dv
                        Selectors
def add rational(x, y):
    nx, dx = numer(x), denom(x)
    ny, dy = numer(y), denom(y)
    return rational(nx * dy + ny * dx, dx * dy)
                                                                             nx*dy + ny*dx
                                                                   ny
                                                        nx
def print rational(x):
    print(numer(x), '/', denom(x))
                                                                   dy
                                                                                 dx*dy
                                                        dx
def rationals_are_equal(x, y):
```

- rational(n, d) returns a rational number x
- numer(x) returns the numerator of x

return numer(x) * denom(y) == numer(y) * denom(x)

denom(x) returns the denominator of x

These functions implement an abstract representation for rational numbers

Representing Pairs Using Lists

```
>>> pair = [1, 2]
                             A list literal:
>>> pair
                              Comma-separated expressions in brackets
[1, 2]
                              "Unpacking" a list
>>> x, y = pair
>>> X
>>> y
>>> pair[0]
                              Element selection using the selection operator
>>> pair[1]
>>> getitem(pair, 0)
>>> getitem(pair, 1)
```

More lists next lecture

Representing Rational Numbers

```
def rational(n, d):
    """A representation of the rational number N/D."""
    return [n, d]
      Construct a list
def numer(x):
    """Return the numerator of rational number X."""
    return x[0]
def denom(x):
    """Return the denominator of rational number X."""
    return x[1]
    Select item from a list
                                        (Demo)
```

10

A Problem of Specification

11

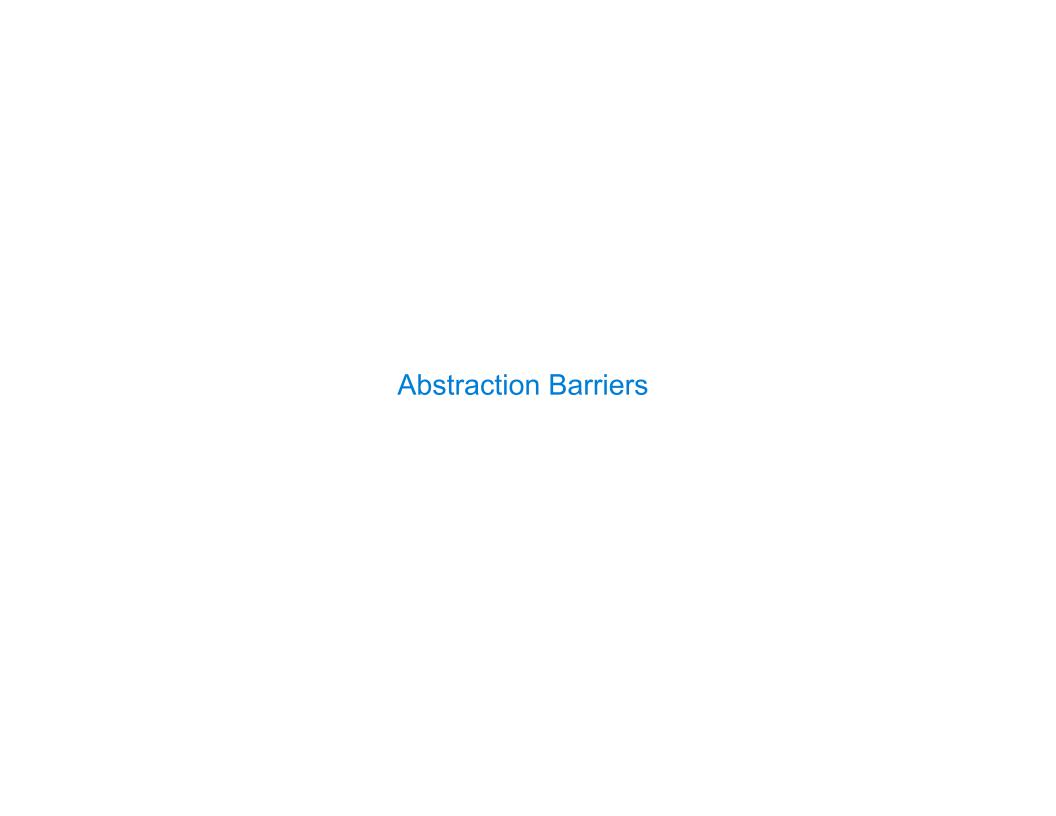

Reducing to Lowest Terms

Example:

$$\frac{3}{2} * \frac{5}{3} = \frac{5}{2} + \frac{1}{10} = \frac{1}{2}$$

$$\frac{15}{6} * \frac{1/3}{1/3} = \frac{5}{2}$$

$$\frac{25}{50} * \frac{1/25}{1/25} = \frac{1}{2}$$

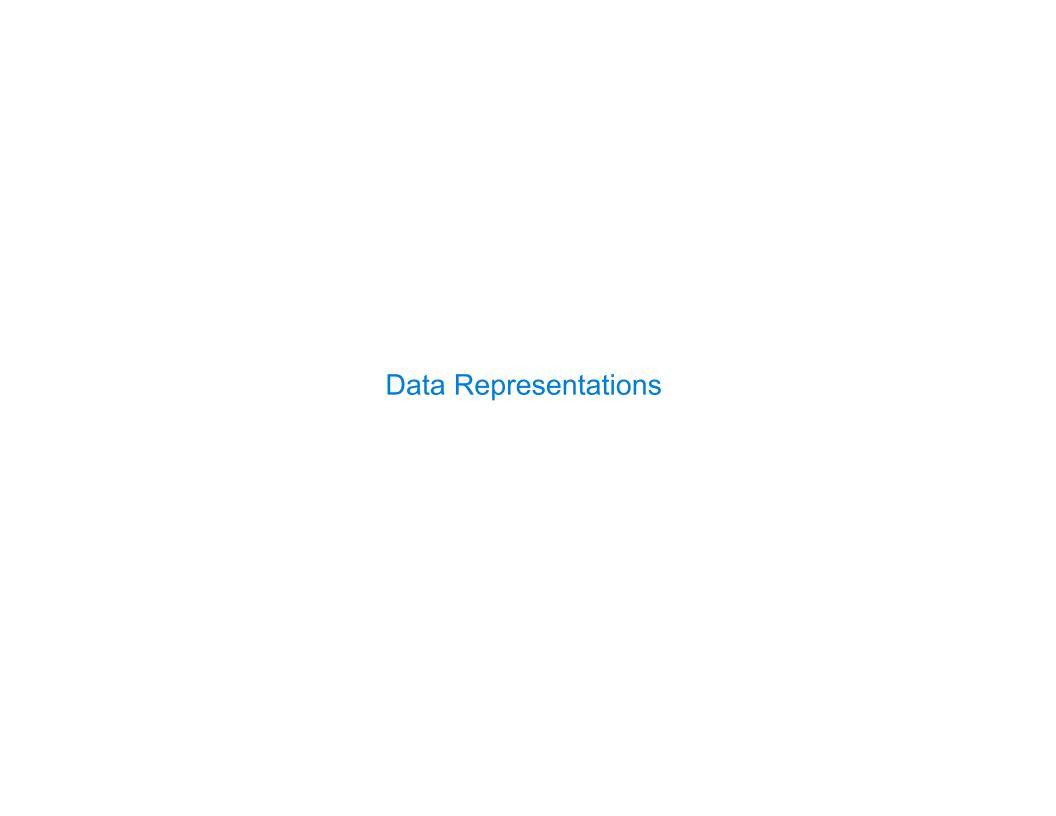

Abstraction Barriers

Parts of the program that	Treat rationals as	Using
Use rational numbers to perform computation	whole data values	<pre>add_rational, mul_rational rationals_are_equal, print_rational</pre>
Create rationals or implement rational operations	numerators and denominators	rational, numer, denom
Implement selectors and constructor for rationals	two-element lists	list literals and element selection
Implementation of lists		

Violating Abstraction Barriers

```
Does not use
                              Twice!
                 constructors
add_rational( [1, 2], [1, 4]
def divide_rational(x, y):
     return [ x[0] * y[1], x[1] * y[0]]
                 No selectors!
                     And no constructor!
```

What is Data?

- We need to guarantee that constructor and selector functions work together to specify the right behavior
- Behavior condition: If we construct rational number x from numerator n and denominator d, then numer(x)/denom(x) must equal n/d
- •Data abstraction uses selectors and constructors to define behavior
- If behavior conditions are met, then the representation is valid

You can recognize an abstract data representation by its behavior

(Demo)

Rationals Implemented as Functions

```
Global frame
                                                                                                                                                                                                                                                                                                                                                                                                  →func rational(n, d) [parent=Global]
def rational(n, d):
                                                                                                                                                                                                                                                                                                                                  rational
                                                                                                                                                                                                                                                                                                                                                                                                  func numer(x) [parent=Global]
                        def select(name):
