

## Trees

## Announcements

### Congratulations to the Winners of the Hog Strategy Contest

1st Place with 146 wins:

A five-way tie for first place!

"A submission scores a match point each time it has an expected win rate strictly above 50.0001%."

**Congratulations** to Timothy Guo, Shomini Sen, Samuel Berkun, Mitchell Zhen, Lucas Clark, Dominic de Bettencourt, Allen Gu, Alec Li, Aaron Janse

## Box-and-Pointer Notation

### The Closure Property of Data Types

- A method for combining data values satisfies the *closure property* if:
  - The result of combination can itself be combined using the same method
- Closure is powerful because it permits us to create hierarchical structures
- Hierarchical structures are made up of parts, which themselves are made up of parts, and so on

Lists can contain lists as elements (in addition to anything else)

### Box-and-Pointer Notation in Environment Diagrams

Lists are represented as a row of index-labeled adjacent boxes, one per element  
Each box either contains a primitive value or points to a compound value

pair = [1, 2]

### Box-and-Pointer Notation in Environment Diagrams

Lists are represented as a row of index-labeled adjacent boxes, one per element  
Each box either contains a primitive value or points to a compound value

```

1 pair = [1, 2]
2
3 nested_list = [[1, 2], [],
4                 [3, False, None],
5                 [4, lambda: 5]]

```

## Slicing

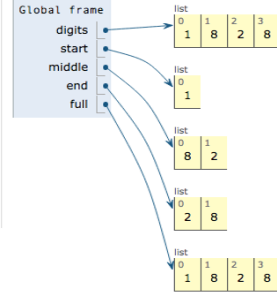

(Demo)

## Slicing Creates New Values

```

1 digits = [1, 8, 2, 8]
2 start = digits[:1]
3 middle = digits[1:3]
4 end = digits[2:]
5 full = digits[:]

```

## Processing Container Values

## Sequence Aggregation

Several built-in functions take iterable arguments and aggregate them into a value

- `sum(iterable[, start])` -> value  
Return the sum of a 'start' value (default: 0) plus an iterable of numbers.
- `max(iterable[, key=func])` -> value  
`max(a, b, c, ..., [, key=func])` -> value  
With a single iterable argument, return its largest item.  
With two or more arguments, return the largest argument.
- `all(iterable)` -> bool  
Return True if `bool(x)` is True for all values `x` in the iterable.  
If the iterable is empty, return True.

## Trees

## Tree Abstraction

### Recursive description (wooden trees):

A tree has a root label and a list of branches  
Each branch is a tree  
A tree with zero branches is called a leaf  
A tree starts at the root

### Relative description (family trees):

Each location in a tree is called a node  
Each node has a label that can be any value  
One node can be the parent/child of another  
The top node is the root node

People often refer to labels by their locations: "each parent is the sum of its children"

## Implementing the Tree Abstraction

```

def tree(label, branches=[]):
    return [label] + branches

def label(tree):
    return tree[0]

def branches(tree):
    return tree[1:]

```

- A tree has a root label and a list of branches
- Each branch is a tree

```

>>> tree(3, [tree(1),
...         tree(2, [tree(1),
...                 tree(1)])])
[3, [1], [2, [1], [1]]]

```

## Implementing the Tree Abstraction

```

def tree(label, branches=[]):
    for branch in branches:
        assert_is_tree(branch)
    return [label] + list(branches)

def label(tree):
    return tree[0]

def branches(tree):
    return tree[1:]

def is_tree(tree):
    if type(tree) != list or len(tree) < 1:
        return False
    for branch in branches(tree):
        if not is_tree(branch):
            return False
    return True

```

Verifies the tree definition

Creates a list from a sequence of branches

Verifies that tree is bound to a list

- A tree has a root label and a list of branches
- Each branch is a tree

```

>>> tree(3, [tree(1),
...         tree(2, [tree(1),
...                 tree(1)])])
[3, [1], [2, [1], [1]]]

```

```

def is_leaf(tree):
    return not branches(tree)
(Demo)

```

## Tree Processing

(Demo)

## Tree Processing Uses Recursion

Processing a leaf is often the base case of a tree processing function  
The recursive case typically makes a recursive call on each branch, then aggregates

```
def count_leaves(t):
    """Count the leaves of a tree."""
    if is_leaf(t):
        return 1
    else:
        branch_counts = [count_leaves(b) for b in branches(t)]
        return sum(branch_counts)
```

(Demo)

## Discussion Question

Implement `leaves`, which returns a list of the leaf labels of a tree  
*Hint: If you `sum` a list of lists, you get a list containing the elements of those lists*

```
>>> sum([ [1], [2, 3], [4] ], [])
[1, 2, 3, 4]
>>> sum([ [1] ], [])
[1]
>>> sum([ [[1]], [2] ], [])
[[1], 2]
```

```
def leaves(tree):
    """Return a list containing the leaf labels of tree.

    >>> leaves(fib_tree(5))
    [1, 0, 1, 0, 1, 1, 0, 1]
    """
    if is_leaf(tree):
        return [label(tree)]
    else:
        return sum([List of leaf labels for each branch, []]
                    [b for b in branches(tree)]
                    [s for s in leaves(tree)]
                    [branches(s) for s in leaves(tree)]
                    [leaves(s) for s in leaves(tree)]])
```

(Demo)

## Creating Trees

A function that creates a tree from another tree is typically also recursive

```
def increment_leaves(t):
    """Return a tree like t but with leaf labels incremented."""
    if is_leaf(t):
        return tree(label(t) + 1)
    else:
        bs = [increment_leaves(b) for b in branches(t)]
        return tree(label(t), bs)
```

```
def increment(t):
    """Return a tree like t but with all labels incremented."""
    return tree(label(t) + 1, [increment(b) for b in branches(t)])
```

(Demo)

## Example: Printing Trees

(Demo)

## Example: Summing Paths
