1 Nonlocal

Until now, you’ve been able to access names in parent frames, but you have not been able to modify them. The nonlocal keyword can be used to modify a binding in a parent frame. For example, consider stepper, which uses nonlocal to modify num:

```python
def stepper(num):
    def step():
        nonlocal num  # declares num as a nonlocal name
        num = num + 1  # modifies num in the stepper frame
        return num
    return step
```

```python
>>> step1 = stepper(10)
>>> step1()  # Modifies and returns num
11
>>> step1()  # num is maintained across separate calls to step
12
>>> step2 = stepper(10)  # Each returned step function keeps its own state
>>> step2()
11
```

As illustrated in this example, nonlocal is useful for maintaining state across different calls to the same function.

However, there are two important caveats with nonlocal names:

- **A variable declared nonlocal** must be defined in a parent frame which is not the global frame.

- **Names in the current frame** cannot be overridden using the nonlocal keyword. This means we cannot have both a local and nonlocal binding with the same name in a single frame.

Because nonlocal lets you modify bindings in parent frames, we call functions that use it **mutable functions**.
Questions

1.1 Write a function that takes in a number \( n \) and returns a one-argument function. The returned function takes in a function that is used to update \( n \). It should return the updated \( n \).

```python
def memory(n):
    """
    >>> f = memory(10)
    >>> f(lambda x: x * 2)
    20
    >>> f(lambda x: x - 7)
    13
    >>> f(lambda x: x > 5)
    True
    """

def f(g):
    ________________________________
    ________________________________
    ________________________________
    return f
```

2 Mutation

Let's imagine you order a mushroom and cheese pizza from La Val’s, and that they represent your order as a list:

```python
>>> pizza = ['cheese', 'mushrooms']
```

A couple minutes later, you realize that you really want onions on the pizza. Based on what we know so far, La Val's would have to build an entirely new list to add onions:

```python
>>> pizza = ['cheese', 'mushrooms']
>>> new_pizza = pizza + ['onions'] # creates a new python list
```

This is silly, considering that all La Val's had to do was add onions on top of pizza instead of making an entirely new pizza.

We can fix this issue with list mutation. In Python, some objects, such as lists and dictionaries, are mutable, meaning that their contents or state can be changed over the course of program execution. Other objects, such as numeric types, tuples, and strings, are immutable, meaning they cannot be changed once they are created.

Therefore, instead of building a new pizza, we can just mutate pizza to add some onions!

```python
>>> pizza.append('onions')
>>> pizza
['cheese', 'mushrooms', 'onions']
```

append is what’s known as a method, or a function that belongs to an object, so we have to call it using dot notation. We’ll talk more about methods later in the course, but for now, here’s a list of useful list mutation methods:

1. append(el): Adds el to the end of the list, and returns None
2. extend(lst): Extends the list by concatenating it with lst, and returns None
3. insert(i, el): Insert el at index i (does not replace element but adds a new one), and returns None
4. remove(el): Removes the first occurrence of el in list, otherwise errors, and returns None
5. pop(i): Removes and returns the element at index i

We can also use the familiar indexing operator with an assignment statement to change an existing element in a list. For example, we can change the element at index 1 and to 'tomatoes' like so:

```python
>>> pizza[1] = 'tomatoes'
>>> pizza
['cheese', 'tomatoes', 'onions']
```
Nonlocal, Mutability, Iterators+Generators

['cheese', 'tomatoes', 'onions']

Questions

2.1 What would Python display? In addition to giving the output, draw the box and pointer diagrams for each list to the right.

```python
>>> s1 = [1, 2, 3]
>>> s2 = s1

>>> s1 is s2

>>> s2.extend([5, 6])

>>> s1[4]

>>> s1.append([-1, 0, 1])

>>> s2[5]

>>> s3 = s2[:]
>>> s3.insert(3, s2.pop(3))

>>> len(s1)

>>> s1[4] is s3[6]

>>> s3[s2[4][1]]

>>> s1[:3] is s2[:3]

>>> s1[:3] == s2[:3]
```
2.2 Fill in the lines below so that the variables in the **global frame** are bound to the values below. Note that the image does not contain a full environment diagram.

**You may only use brackets, commas, colons, \ p\ , and \ q\ in your answer.**

```python
def mystery(p, q):
    p[1].extend(_______________________________)
    __________________________.append(____________________[1:]_)

p = [2, 3]
q = [4, [p]]
mystery(_______________, _________________)
```

Note: This worksheet is a problem bank—most TAs will not cover all the problems in discussion section.
2.3 Tutorial: Write a function that takes in a sequence $s$ and a function $fn$ and returns a dictionary.

The values of the dictionary are lists of elements from $s$. Each element $e$ in a list should be constructed such that $fn(e)$ is the same for all elements in that list. The key for each value should be $fn(e)$. For each element $e$ in $s$, check the value that calling $fn(e)$ returns, and add $e$ to the corresponding group.

```python
def group_by(s, fn):
    """
    >>> group_by([12, 23, 14, 45], lambda p: p // 10)
    {1: [12, 14], 2: [23], 4: [45]}
    >>> group_by(range(-3, 4), lambda x: x * x)
    {9: [-3, 3], 4: [-2, 2], 1: [-1, 1], 0: [0]}
    """
    grouped = {}
    for ________________:
        key = ________________
        if ____________________________:
            ________________________________
        else:
            grouped[key] = ____________________________
    return ________________________________
```

Note: This worksheet is a problem bank—most TAs will not cover all the problems in discussion section.
2.4 Tutorial: Write a function that takes in a value \( x \), a value \( el \), and a list \( s \) and adds as many \( el \)’s to the end of the list as there are \( x \)’s. Make sure to modify the original list using list mutation techniques.

```python
def add_this_many(x, el, s):
    """ Adds el to the end of s the number of times x occurs in s. """
    >>> s = [1, 2, 4, 2, 1]
    >>> add_this_many(1, 5, s)
    >>> s
    [1, 2, 4, 2, 1, 5, 5]
    >>> add_this_many(2, 2, s)
    >>> s
    [1, 2, 4, 2, 1, 5, 5, 2, 2]
```

*Note: This worksheet is a problem bank—most TAs will not cover all the problems in discussion section.*
3 Iterators

An iterable is a data type which contains a collection of values which can be processed one by one sequentially. Some examples of iterables we’ve seen include lists, tuples, strings, and dictionaries. In general, any object that can be iterated over in a for loop can be considered an iterable.

While an iterable contains values that can be iterated over, we need another type of object called an iterator to actually retrieve values contained in an iterable. Calling the iter function on an iterable will create an iterator over that iterable. Each iterator keeps track of its position within the iterable. Calling the next function on an iterator will give the current value in the iterable and move the iterator’s position to the next value.

In this way, the relationship between an iterable and an iterator is analogous to the relationship between a book and a bookmark - an iterable contains the data that is being iterated over, and an iterator keeps track of your position within that data.

Once an iterator has returned all the values in an iterable, subsequent calls to next on that iterable will result in a StopIteration exception. In order to be able to access the values in the iterable a second time, you would have to create a second iterator. One important application of iterables and iterators is the for loop. We’ve seen how we can use for loops to iterate over iterables like lists and dictionaries.

This only works because the for loop implicitly creates an iterator using the built-in iter function. Python then calls next repeatedly on the iterator, until it raises StopIteration.

The code to the right shows how we can mimic the behavior of for loops using while loops.

Note that most iterators are also iterables - that is, calling iter on them will return an iterator. This means that we can use them inside for loops. However, calling iter on most iterators will not create a new iterator - instead, it will simply return the same iterator.

We can also iterate over iterables in a list comprehension or pass in an iterable to the built-in function list in order to put the items of an iterable into a list.

In addition to the sequences we’ve learned, Python has some built-in ways to create iterables and iterators. Here are a few useful ones:

- **range(start, end)** returns an iterable containing numbers from start to end-1. If start is not provided, it defaults to 0.
- **map(f, iterable)** returns a new iterator containing the values resulting from applying f to each value in iterable.
- **filter(f, iterable)** returns a new iterator containing only the values in iterable for which f(value) returns True.

```python
>>> a = [1, 2]
>>> a_iter = iter(a)
>>> next(a_iter)
1
>>> next(a_iter)
2
>>> next(a_iter)
StopIteration

counts = [1, 2, 3]
for i in counts:
    print(i)

# equivalent to following pseudocode
# items = iter(counts)
# while True
#     if next(items) errors
#         exit the loop
#     i = the value that returned
#     print(i)
```
Questions

3.1 What would Python display?

```python
>>> s = [[1, 2]]
>>> i = iter(s)
>>> j = iter(next(i))
>>> next(j)

>>> s.append(3)
>>> next(i)

>>> next(j)

>>> next(i)
```
4 Generators

A generator function is a special kind of Python function that uses a yield statement instead of a return statement to report values. When a generator function is called, it returns a generator object, which is a type of iterator. To the right, you can see a function that returns an iterator over the natural numbers.

The yield statement is similar to a return statement. However, while a return statement closes the current frame after the function exits, a yield statement causes the frame to be saved until the next time next is called, which allows the generator to automatically keep track of the iteration state.

Once next is called again, execution resumes where it last stopped and continues until the next yield statement or the end of the function. A generator function can have multiple yield statements.

Including a yield statement in a function automatically tells Python that this function will create a generator. When we call the function, it returns a generator object instead of executing the body. When the generator’s next method is called, the body is executed until the next yield statement is executed.

When yield from is called on an iterator, it will yield every value from that iterator. It’s similar to doing the following:

```python
for x in an_iterator:
    yield x
```

The example to the right demonstrates how to use generators to output natural numbers.

```python
>>> def gen_naturals():
...     current = 0
...     while True:
...         yield current
...         current += 1

>>> gen = gen_naturals()
>>> gen
<generator object gen at ...>
>>> next(gen)
0
>>> next(gen)
1
```
Questions

4.1 Implement a generator function called `filter(iterable, fn)` that only yields elements of iterable for which `fn` returns True.

```python
def filter(iterable, fn):
    """
    >>> is_even = lambda x: x % 2 == 0
    >>> list(filter(range(5), is_even))  # a list of the values yielded from the call to filter
    [0, 2, 4]
    >>> all_odd = (2*y-1 for y in range(5))
    >>> list(filter(all_odd, is_even))
    []
    >>> naturals = (n for n in range(1, 100))
    >>> s = filter(naturals, is_even)
    >>> next(s)
    2
    >>> next(s)
    4
    """
```

Note: This worksheet is a problem bank—most TAs will not cover all the problems in discussion section.
4.2 **Tutorial:** Write a generator function `merge` that takes in two infinite generators `a` and `b` that are in increasing order without duplicates and returns a generator that has all the elements of both generators, in increasing order, without duplicates.

```python
def merge(a, b):
    """
    >>> def sequence(start, step):
    ...     while True:
    ...         yield start
    ...         start += step
    >>> a = sequence(2, 3)  # 2, 5, 8, 11, 14, ...
    >>> b = sequence(3, 2)  # 3, 5, 7, 9, 11, 13, 15, ...
    >>> result = merge(a, b)  # 2, 3, 5, 7, 8, 9, 11, 13, 14, 15
    >>> [next(result) for _ in range(10)]
    [2, 3, 5, 7, 8, 9, 11, 13, 14, 15]
    """
    """
```
