# Announcements

- HW11 due Wednesday
- Scheme project, contest out

# Our Sequence Abstraction

Recall our previous sequence interface:

- A sequence has a finite, known length
- A sequence allows element selection for any element

In most cases, satisfying the sequence interface requires storing the entire sequence in a computer's memory

Problems?

- Infinite sequences- primes, positive integers
- Really large sequences- all Twitter posts, votes in a presidential election

# The Sequence of Primes

Think about the sequence of prime numbers:

- What's the first one?
- The next one?
- The next one?
- How about the next two?
- How about the 105<sup>th</sup> prime?
  - Our sequence abstraction would give an instant answer

# Implicit Sequences

- We compute each of the elements on demand.
- Don't explicitly store each element
- Called an **implicit sequence**.

# A Python Example

**Example:** The `range` class represents a regular sequence of integers

- The range is represented by three values: *start*, *end*, and *step*
- The length and elements are computed on demand
- Constant space for arbitrarily long sequences

$$length = \max \left( \left\lceil \frac{end - start}{step} \right\rceil, 0 \right)$$

$$elem(k) = start + k \cdot step \quad (\text{for } k \in [0, length))$$

# A Range Class

```
class Range(object):
    def __init__(self, start, end=None, step=1):
        if end is None:
            start, end = 0, start
        self.start = start
        self.end = end
        self.step = step

    def __len__(self):
        return max(0, ceil((self.end - self.start) /
                           self.step))

    def __getitem__(self, k):
        if k < 0:
            k = len(self) + k
        if k < 0 or k >= len(self):
            raise IndexError('index out of range')
        return self.start + k * self.step
```

# The Iterator Interface

An iterator is an object that can provide the next element of a (possibly implicit) sequence

The iterator interface has two methods:

- `__iter__(self)` returns an equivalent iterator.
  - Recite prime numbers.
- `__next__(self)` returns the next element in the sequence
  - Next prime, etc.
  - If no next, raises `StopIteration` exception.

# Rangelter

```
class RangeIter(object):
    def __init__(self, start, end, step):
        self.current = start
        self.end = end
        self.step = step
        self.sign = 1 if step > 0 else -1

    def __next__(self):
        if self.current * self.sign >= self.end * self.sign:
            raise StopIteration
        result = self.current
        self.current += self.step
        return result

    def __iter__(self):
        return self
```

# Fibonacci

```
class FibIter(object):
    def __init__(self):
        self.prev = -1
        self.current = 1

    def __next__(self):
        self.prev, self.current = (self.current,
                                    self.prev + self.current)

        return self.current

    def __iter__(self):
        return self
```

# The For Statement

```
for <name> in <expression>:  
    <suite>
```

1. Evaluate the header **<expression>**, which yields an iterable object.
2. For each element in that sequence, in order:
  - A. Bind **<name>** to that element in the first frame of the current environment.
  - B. Execute the **<suite>**

An iterable object has a method `__iter__` that returns an iterator

```
>>> nums, sum = [1, 2, 3], 0  
>>> for item in nums:  
    sum += item  
>>> sum  
6  
  
>>> nums, sum = [1, 2, 3], 0  
>>> items = nums.__iter__()  
>>> try:  
    while True:  
        item = items.__next__()  
        sum += item  
except StopIteration:  
    pass  
>>> sum  
6
```

# Generators and Generator Functions

## Generators:

- An iterator backed by a function, called a **generator function**.

## Generator Functions:

- A function that returns a generator.
- Can tell by looking for the **yield** keyword.
- Another example of a *continuation*

# Fibonacci Generator

A generator function that lazily computes the Fibonacci sequence:

```
def fib_generator():  
    yield 0  
    prev, current = 0, 1  
    while True:  
        yield current  
        prev, current = current, prev + current
```

A generator expression is like a list comprehension, but it produces a lazy generator rather than a list:

```
double_fibs = (fib * 2 for fib in fib_generator())
```

# Generator Semantics

```
def fib_generator():  
    yield 0  
    prev, current = 0, 1  
    while True:  
        yield current  
        prev, current = current, prev + current
```

Calling a generator function returns an iterator that stores a frame for the function, its body, and the current location in the body

Calling **next** on the iterator resumes execution of the body at the current location, until a **yield** is reached

The yielded value is returned by **next**, and execution of the body is halted until the next call to **next**

When execution reaches the end of the body, a **StopIteration** is raised

# Map and Filter

```
def map_gen(fn, iterable):
    iterator = iter(iterable)
    while True:
        yield fn(next(iterator))
```

```
def filter_gen(fn, iterable):
    iterator = iter(iterable)
    while True:
        item = next(iterator)
        if fn(item):
            yield item
```

# Bitstring Generator

```
from itertools import product

def bitstrings():
    """Generate bitstrings in order of increasing
    size.

    >>> bs = bitstrings()
    >>> [next(bs) for _ in range(0, 8)]
    ['', '0', '1', '00', '01', '10', '11', '000']
    """
    size = 0
    while True:
        tuples = product('0', '1', repeat=size)
        for elem in tuples:
            yield ''.join(elem)
        size += 1
```
