

## 61A LECTURE 19 – CALCULATOR

Steven Tang and Eric Tzeng  
July 25, 2013

### Turtle graphics

- STk has built in support for basic 2D graphics!
- Turtle sits on the canvas
- As the turtle “walks” around the canvas, it leaves a trail
- Images are drawn by issuing commands to the turtle

```
(define (triangle)
  (forward 100)
  (right 120)
  (forward 100)
  (right 120)
  (forward 100)
  (right 120))
```

Move forward 100 steps

Turn right 120 degrees

- Did we need the last call to `right`? Why?

### The Begin Special Form

Begin expressions allow sequencing

```
(begin <exp1> <exp2> ... <expn>)

(define (repeat k fn)
  (if (> k 0)
      (begin (fn) (repeat (- k 1) fn))
      'done))

(define (tri fn)
  (repeat 3 (lambda () (fn) (lt 120))))

(define (sier d k)
  (tri (lambda () (if (= k 1) (fd d) (leg d k)))))

(define (leg d k)
  (sier (/ d 2) (- k 1)) (penup) (fd d) (pendown))
```

### You are now Scheme masters!

- That wraps up our discussion of Scheme
- From here on out, the focus is going to be on interpreters
- In other words, we’re writing programs that understand programs!

### Programming Languages

Computers have software written in many different languages

Machine languages: statements can be interpreted by hardware

- All data are represented as a sequence of bits
- All statements are primitive instructions

High-level languages: hide concerns about those details

- Primitive data types beyond just bits
- Statements/expressions, data can be non-primitive (e.g. calls)
- Evaluation process is defined in software, not hardware

High-level languages are built on top of low-level languages

Machine  
Language

C

Python

### Metalinguistic Abstraction

**Metalinguistic abstraction:** Establishing new technical languages (such as programming languages)

$$f(x) = x^2 - 2x + 1$$

$$\lambda f. (\lambda x. f(x x)) (\lambda x. f(x x))$$

In computer science, languages can be *implemented*:

- An *interpreter* for a programming language is a function that, when applied to an expression of the language, performs the actions required to evaluate that expression
- The *semantics* and *syntax* of a language must be specified precisely in order to build an interpreter

### The Scheme-Syntax Calculator Language

A subset of Scheme that includes:

- Number primitives
- Built-in arithmetic operators: +, -, \*, /
- Call expressions

```
> (+ (* 3 5) (- 10 6))
19
> (+ (* 3
      (+ (* 2 4)
          (+ 3 5)))
      (+ (- 10 7)
          6))
57
```

### Syntax and Semantics of Calculator

**Expression types:**

- A **call expression** is a Scheme list
- A **primitive expression** is an operator symbol or number

**Operators:**

- The + operator returns the sum of its arguments
- The - operator returns either
  - the additive inverse of a single argument, or
  - the sum of subsequent arguments subtracted from the first
- The \* operator returns the product of its arguments
- The / operator returns the real-valued quotient of a dividend and divisor (i.e. a numerator and denominator)

### Today...

- We're going to write an interpreter for this language
- And we're going to do it from (almost) scratch!
  - We're going to reuse some Rlist functions that you've seen before
- You know how to do everything in this lecture already!
- We're just putting it together

### Reading Scheme Lists

A Scheme list is written as elements in parentheses:

Each **<element>** can be a combination or primitive

```
(+ (* 3 (+ (* 2 4) (+ 3 5))) (+ (- 10 7) 6))
```

The task of *parsing* a language involves coercing a string representation of an expression to the expression itself

Parsers must validate that expressions are well-formed

### Parsing

A parser takes a sequence of lines and returns an expression.

```
'(+ 1 (- 23) (* 4 5.6))'
      |
      v
('(', '+', 1
 '(', '-', 23, ')',
 '(', '*', 4, 5.6, ')', ')')
      |
      v
Pair('+', Pair(1, ...))
      |
      v
(+ 1 (- 23) (* 4 5.6))
      |
      v
printed as
(+ 1 (- 23) (* 4 5.6))
```

- Iterative process
- Checks for malformed tokens
- Determines types of tokens

- Tree-recursive process
- Balances parentheses
- Returns tree structure

### Lexical analysis

- It's hard to directly determine the program structure from a string

- Split the string into a sequence of "tokens"
- From the token sequence, it's a lot easier to determine the program structure

## Syntactic Analysis

Syntactic analysis identifies the hierarchical structure of an expression, which may be nested.

Each call to `read_exp` consumes the input tokens for exactly one expression.

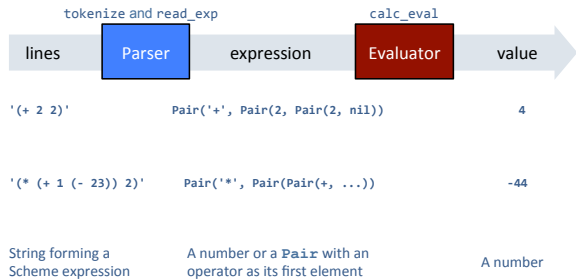

```
'(', '+', 1, '(', '-', 23, ')', '(', '*', 4, 5.6, ')', ')'
```

**Base case:** symbols and numbers

**Recursive call:** call `read_tail`, which uses `read_exp` for sub-expressions and combines them as pairs

## Expression Trees

A basic interpreter has two parts: a parser and an evaluator

## Evaluation

Evaluation discovers the form of an expression and then executes a corresponding evaluation rule

Primitive expressions are evaluated directly

Call expressions are evaluated recursively:

- Evaluate each operand expression
- Collect their values as a list of arguments
- Apply the named operator to the argument list

## Applying Operators

Calculator has a fixed set of operators that we can enumerate

```
def calc_apply(op, args):
    """Apply an operator to a list of args."""
    if operator == '+':
        return ...
    if operator == '-':
        ...
    ...
```

Dispatch on operator name

## Raising Application Errors

The `-` and `/` operators have restrictions on argument number

Raising exceptions in `apply` can identify such issues

```
def calc_apply(op, args):
    """Apply an operator to a list of args."""
    if op == '-':
        if len(args) == 0:
            raise TypeError('Not enough arguments')
        ...
    if op == '/':
        if len(args) == 2:
            raise TypeError('Not enough arguments')
        ...
```

## Read-Eval-Print Loop

The user interface to many programming languages is an interactive loop, which

- Reads an expression from the user,
- Parses the input to build an expression tree,
- Evaluates the expression tree,
- Prints the resulting value of the expression

The REPL handles errors by printing informative messages for the user, rather than crashing

A well-designed REPL should not crash on any input!
